The large iron moor deposits of Pyrmont spread over miles of ground in all directions from the the old *Hyllige Born* and the *Helenensource* are technically so perfectly prospected that the water may be filled into the glasses without the slightest change or deterioration of its original constituent form. The popularity of the drinking cure has compelled the management to build a new spring house and an enclosed promenade in which the visitor may take exercise while drinking the waters even in bad or rainy weather.

Pyrmont has two bath establishments and a Kurhaus. The socalled lower bathhouse, built at a time when the demands were more modest and tastes more simple, has now been provided with all the latest technical innovations. This bath establishment lies about a mile from the centre of the town; it is surrounded by beautiful lawns and is easily accessible by means of street car connections. The upper bath establishment lies in the centre of the village. Its monumental exterior, its artistic trim, and its high class appurtenances make it one of the most luxurious yet refined establishments of its kind. Each bath

Fig. 3.—In the Kurpark

cubicle is steamheated, ventilated, and supplied with clock, linen, warming apparatus, etc. Heavy rugs in all the hallways deaden the sound. The required personnel is summoned by electric light sign system instead of by bells, so as to insure complete restfulness. A special heating system which reduces the loss of carbonic acid gas to an infinitesimal percentage has been provided for the warming of the bath water. This bath establishment has 143 bath cells and offers steel, saline and mixed baths, the latter Pyrmont's specialty. Twenty-nine cubicles are fitted for moor baths and fifteen for moor packs. For patients who are unable to move about special bath cells with appropriate appliances have been installed.

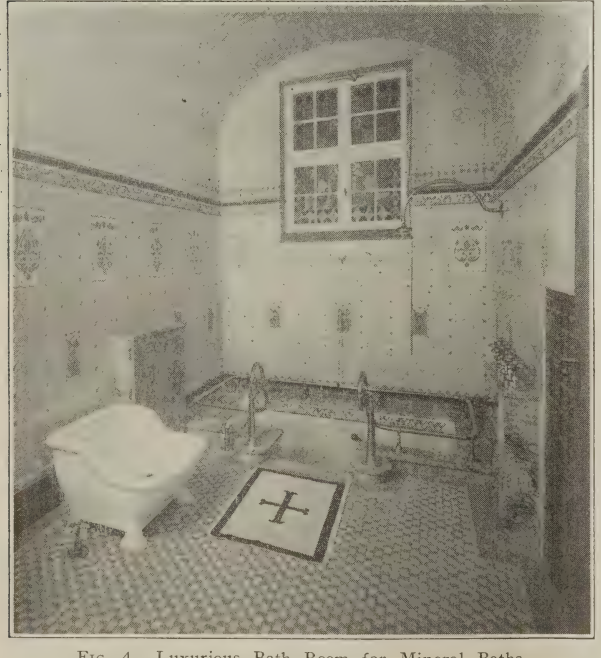

Fig. 4.—Luxurious Bath Room for Mineral Baths

The *Kurhaus* proper has bath cells adjoining the rooms, so arranged as to allow of the giving of all mineral water baths. The Kurhaus is connected with the upper bath establishment by an arcade, and the guests at the former may reach the bath building without going outside.

A number of medicomechanical installations for the removal of curvatures, especially such as those occasioned through war injuries, have been placed in a special room in the upper bath building. Electric light and electric water baths of every description and artificial sunbaths are also given here under medical supervision. One large hall has been set aside for inhalatory treatments. Special cubicles are so arranged as to permit the individual regulation of temperatures during and after treatments, thus avoiding the danger of relaxed mucous membranes and preventing further colds. As usual, a pneumatic machine controls the various degrees of condensed air prescribed for inhalation in cases of lung, heart and ear troubles. A separate inhalatorium for more general use may be found in a detached building, delightfully located in the *Kurpark*.

All the latest medical instruments may be found

Fig. 5.—Resting on the lawn

in Pyrmont: electrical machines for faradization and galvanization, the electric cardiograph and the many varied appliances for hot air treatments, four cell baths, x ray photography, and x ray treatments.

The curative properties of the Pyrmont springs are well defined and firmly established. Their main functions are indicated in all cases of diseased conditions of the blood, the circulation, nerves, female disorders and metabolism.

Even before iron had been established as an essential factor in the cures of blood diseases or before the Pyrmont main spring had been analyzed, the latter had gained a reputation as eminently restorative in cases of anemia of every description. Gout and all manner of gouty conditions, as well as obesity,

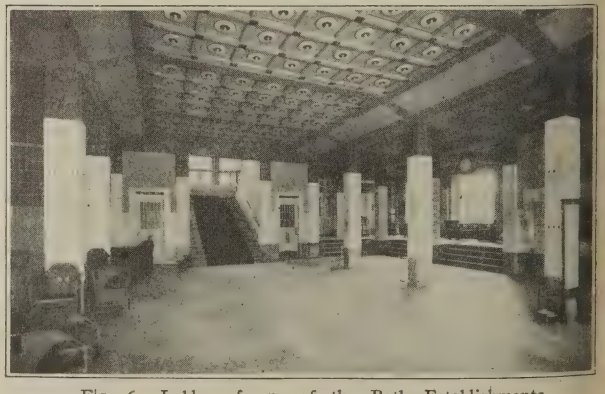

Fig. 6.—Lobby of one of the Bath Establishments

are some of the most important medical indications of Pyrmont. Experiments made at Berlin laboratories with Pyrmont salines have yielded the most convincing results in clearing the human system of the injurious nitrogenous combinations. The results attained through these experiments were enhanced by the use of baths and packs of Pyrmont moor. The humid warmth engendered by the applications of the medicinal earths (moor, fengo, etc.) dissolves the gouty deposits, which are then eliminated by the drinking of the Pyrmont salines.

A similar result is obtained by the use of Pyrmont moor applications in cases of infections, adhesions, or the consequences of acute inflammations. Hence disorders of the female sexual organs, deposits following an acute inflammatory rheumatism, nervous disorders consequent upon growths or other anatomical abnormalities, ischias, paralyses resulting from inflammation of the nerves, or from injuries, as well as chronic rheumatism are immensely benefitted by a cure at Pyrmont.

Since the fact has been established that heart troubles are successfully treated with baths of water highly impregnated with carbonic acid, the number of patients that come yearly to Pyrmont for the treatment of heart ailments is steadily increasing. Remarkable results have been obtained in Pyrmont in all heart indications.

Hysteria, all inclinations to chorea or similar conditions are satisfactorily treated through Pyrmont saline waters, which are also considered a preventive of appendicitis. Many cases of apparent sterility have been successfully overcome through a course of treatment at Pyrmont.

In addition to the facilities connected with its own distinctive medical indications, Pyrmont offers every facility and the most modern equipment for the treatment of most of the ailments for which cures are sought in the best known watering places of the world.

Besides the curative merits of Pyrmont, its charm as one of the most delightful and refined resorts of Europe should not be overlooked.

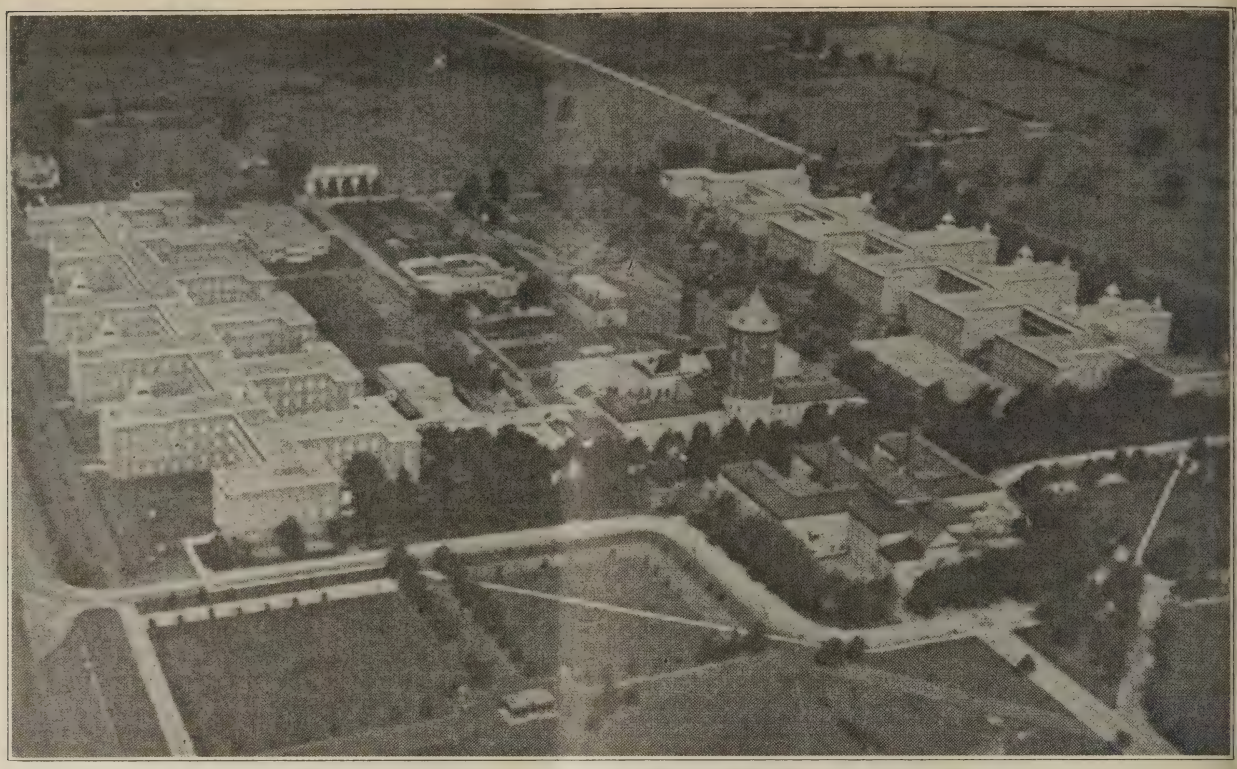
Ample provision for entertainment and for recreation has been provided for visitors. Concerts, operatic and theatrical performances of the very best, musicales and balls follow on days of outdoor sports. There is fine fishing, good golf, trap shooting and hunting in the vast well stocked preserves, while Pyrmont's tennis tournaments, horse shows, and automobile and horse races are among the best known sporting features of German life.

Annual Clinical Congress of American College of Surgeons

On Monday morning of October 5, 1926, the sixteenth annual Clinical Congress of the American College of Surgeons convened in the Windsor Hotel, Montreal. Than Montreal few cities of this continent are better adapted for the holding of such a meeting. It is admittedly the convention city of Canada, on account of its good railway facilities, its size and importance as the second largest port of North America and as a distributing centre, its picturesque situation and its lovely surroundings and the number, capacity and equipment of its hotels. Montreal possesses that flavor or halo of age and tradition which appeals to that sentimental side of the American character which is one of its predominant features. For a surgical meeting Montreal is adapted peculiarly well. It contains many large and excellently up to date hospitals, as well as special hospitals which reach a high standard of efficiency.

Not the least of its outstanding qualifications are its French-Canadian hospitals. The French were

Royal Victoria Hospital



Hôpital Saint-Jean-de-Dieu

the pioneers of Canada and its earliest settlers. Maisonneuve, or rather one of his wonderful women coworkers, Jeanne de Mance, founded the Hôpital Dieu in the earlier days of Mont Real. The French speaking population constitute the majority of the inhabitants of Montreal, and their hospitals, for the most part are of a religious as of a medical and surgical character, and whose nursing staffs are composed of sisters.

OPENING SESSION

The following account of the meeting of the American College of Surgeons will be more of a discursive and chatty than of a strictly scientific nature. It should, at once, be emphasized that these clinical congresses are really what their name denotes and their object above all is practical, that is to teach and afford information. Social functions do not come within the scope of the Congress, the slogan is business first. On the morning of October 25th, the opening session was held in the Windsor Hall of the Windsor Hotel under the chairmanship of Dr. Rudolph Matas, the retiring president. This meeting was concerned with the hospital question, the standardization of hospitals being one of the main objects to which Dr. Franklin Martin, the Director General of the American College of Surgeons, has directed his boundless energy and powers of organization assisted it may be said by associates whom he has imbued with his own enthusiasm, and who vie with him in the attempt to reach the goal.

Dr. A. K. Haywood, superintendent of the Montreal General Hospital and chairman of the Montreal Hospital Congress, delivered the opening address. Dr. Haywood gave an outline of the organization and work of the Montreal hospitals, pointing out that as the case is with many other cities owing to the rapid growth of Montreal and its consequently growing needs, all the hospitals were crowded.

General Sir Arthur Currie, president of McGill University, said, in part, that there was no science which had such a practical bearing upon the relief of human ills as that of medicine and surgery. It had been said that public health was the foundation of the happiness of a people and the power of a country. He wished that all our statesmen, real or imaginary, would be willing to take this advice and follow it. The war had disclosed the appalling number of physically unfit, and this was due largely to the lack of interest in public health, not the fault of the medical men, but of the state's indifference. One of the most interesting speeches was by Prof. David P. D. Wilkie, of Edinburgh, who discussed the British hospital problem. He characterized the standardization of hospitals as a landmark in medical history. It meant bringing the latest discoveries of medical science within the reach of all men rich or poor. The high standard achieved in most American hospitals, he said, was the best possible tribute to the effectiveness of this movement. A big problem existed in regard to the small hospitals. He thought that by linking up with larger institutions the small hospitals would not lose their individuality, and would gain many of the advantages of the larger hospitals. In Britain the problem was difficult. There were hospitals for indigent patients where nothing was paid, and there were many costly institutions where the wealthy were cared for in sickness and paid heavily for it. There was a class in between these two which was not provided for at all. The better class workingman, who scorned anything tainted with charity, and yet could not pay the high fees of costly nursing

homes, had no place to go for nursing and hospital care. The only remedy for this condition, he thought, was to be found in a scheme of standardization.

Owing to limited space, and to an embarrassment of riches in the way of papers, addresses, speeches, and clinical meetings and demonstrations, many features of great interest and value must be left untouched or discussed only cursorily.

NEW PRESIDENT

The instalment of the new president, Dr. Walter W. Chipman, of Montreal, was one of the *bonnes bouches* of the meeting. This ceremonial function took place on the evening of October 25th, in the Windsor Hall. The ceremony was impressive. The massive mace presented to the college by the consulting surgeons to the British armies at the front during the Great War was borne by a stalwart lieutenant of the Duke of York's Royal Canadian Horse, at the head of a procession of distinguished Fellows of the college, eminent visitors and foreign guests, and laid down on a table on the platform draped by the Union Jack. Among the thirty present on the platform were Dr. Franklin Martin, the Director General, and other well known American and Canadian surgeons, and ten distinguished guests. Dr. A. Bazin, of Montreal General Hospital, and chairman of committee on arrangements, on behalf of the resident profession of Montreal welcomed the College of Surgeons to the city. Sir Arthur Currie, principal of McGill University, followed with a thoughtful address, and then the retiring president, Dr. Rudolph Matas, gave an eloquent speech, in the course of which he made special mention of the honor paid to the College by the presence of two Regius Professors of the chief Scottish universities, welcoming them to a spot where "the heather and the thistle seem to grow apace with the maple and the fleur-de-lis, with McGill University proclaiming the strength and stability of Scottish tradition and culture."

Prof Roberto Alessandri, Rome, Italy. Mr. A. Sampson Handley, Surgeon to Middlesex Hospital, London, England

The title of the address was Surgery and the International Spirit, the tenor of the entire address was to the effect that science, in which, of course, medical science is included, knows no boundaries. He referred to Pasteur and Lister as the two greatest benefactors in medical science to the human race and emphasized his statement by giving the following paraphrase of a well known saying, "I am a surgeon and nothing human is foreign to me." At the conclusion of his address Dr. Matas invested his successor, Dr. Walter W. Chipman, of Montreal, with the robes of office. Dr. Chipman's first official duty was to call upon Dr. Franklin Martin to introduce the distinguished guests. These were: Prof. David P. D. Wilkie, Edinburgh, Scotland; Prof. Roberto Alessandri, Rome, Italy; Sir Ewen Maclean, Cardiff, Wales; Prof. Archibald Young, Glasgow, Scotland; Prof. John M. C. Fraser, Edinburgh, Scotland; Mr. W. Sampson-Handley, London, England; Prof. Louis E. Barnett, Dunedin, New Zealand; Prof. Ricardo Palma, Lima, Peru, which by the way is the oldest university on these continents; Prof. Rudecende da la Fuente, Valparaiso, Chile, and Prof. Luis de Rezenie Puech, San Paulo, Brazil.

In his presidential address Dr. Chipman discussed cancer prophylaxis. There is not space here to deal with Dr. Chipman's address at length; it will be referred to thus later. It must suffice to say that he pointed out that there was a growing knowledge of the disease and that a way of salvation might soon be opened from one of the greatest scourges of human life. He quoted statistics which went to show that there were eighty thousand deaths in the United States from cancer each year, and that Canada was a heavy sufferer. He gave a working hypothesis, to the effect that cancer was brought about more probably by growth and decay than by an organism. The moral, therefore, was to keep young as long as possible and as age is a question of tissues not of years, it behooved us to lead more simple and frugal lives, to eat less, to drink less of fluids other than water, and to drink much water between meals.

The final address of the evening was the John B. Murphy oration in surgery which was given by Professor Archibald Young, of Glasgow. Professor Young chose as the subject of his address a sketch and a somewhat intimate sketch of one of the greatest surgeons and original thinkers who ever lived, Sir William Macewen. It also dealt with his important influence on the evolution and development of the Glasgow School of Surgery.

(*To be continued*)

News Items.

Nobel Prize Winner in Medicine.—The Nobel Prize in Medicine has been awarded to Prof. Johannes Fibiger of the University of Copenhagen. Professor Fibiger has distinguished himself by researches in both cancer and tuberculosis, and was the winner in 1924 of the Jung cancer research award.

Hungarian Experts Studied New York State Methods.—Among the distinguished foreign visitors who last year studied health administrative procedures in this country, says *Health News,* was Dr. F. Kiss of Hungary. He was present as an interested observer at the health officers' course held in Watertown, N. Y. Dr. A. C. Gaal, assistant at the Hygienic Institute in Budapest also visited the New York State Department of Health to study methods. Dr. Kiss has been instrumental in starting a health officers' course in Sarospatak.

Lectures on Child Health.—A series of fifteen lectures on the Child and His Needs, a practical course on the mental health of children, is being given at the Boston University College of Liberal Arts Building, under the direction of the University School of Education, according to the *Mental Hygiene Bulletin.* J. Mace Andress, Ph.D., is in charge of the series, assisted by experts on various phases of child health. These lectures began in September and are being held on successive Tuesday evenings. This course, which is similar to ones that have been given during the last few years at the university, includes lectures by Dr. Douglas A. Thom, Ernest R. Groves, Ph.D., Dr. Karl M. Bowman, Dr. Ransom M. Greene, Dr. Abraham Myerson, Augusta F. Bronner, Ph.D., Dr. George K. Pratt, Arthur H. Kallom, John M. Brewer, Ph.D., Dr. Henry B. Elkind, Dr. William Healy, and J. Mace Andress, Ph.D.

New Lutheran Hospital Plans.—Announcement has recently been made of further details of the plans for the building of the Lutheran Hospital, to be erected at West 178th Street and Bennett Avenue, New York City. The cost of the building, exclusive of site and equipment, will be $750,000. It will be eight stories in height. The first floor will house the administration offices and dispensary rooms, and the floors above will be devoted to the wards, private and semi-private rooms, operating rooms, and several laboratories. One of the chief features of the building will be the smallness of its wards. The largest will be limited to nine beds, and four will be the number in most of them. Every room is to have direct sunshine during most of the day. There will be a children's department with a large play room. A laundry and power plant will be housed in a separate building. An ultimate capacity of 600 beds is being planned for, with a separate building for nurses. The hospital will maintain its present plant at 144th Street and Convent Avenue until such a time as that neighborhood is cared for by another institution.

Dinner in Honor of Major Bocchetti.—A dinner attended by forty-eight men was given at the Union League Club, New York City, by Dr. William Seaman Bainbridge recently in honor of Major Federigo Bocchetti of the Italian Army Medical Corps. Major Bocchetti is also director of the Military Tuberculosis Sanatorium at Anzio, and was delegate from Italy to the recent International Congress for the Control of Tuberculosis held in Washington, and to the meeting of the Association of Military Surgeons of the United States held in Philadelphia. The dinner was tendered in honor also of the other foreign delegates to these congresses who were visitors in New York City. In addition it was a recognition, through honoring Major Bocchetti, of Italy's courtesy to the American delegate to the Second International Congress of Military Medicine and Surgery, held in Rome in 1923, and of the leader of the Military Medical Service of Italy, General Bella Valle. Dr. Bainbridge acted as toastmaster. The speakers included Admiral Charles P. Plunkett, U. S. N.; Col. José Izquierdo, Surgeon General of the Venezuelan Army; Major Murad Bey, of the Turkish Army Medical Corps; Lt. Col. Mario Adami, of the Medical Service of the Royal Italian Army; Dr. M. Santovicenzo, Royal Italian Vice Consul; Dr. Antonio Stella, and Count Thaon di Revel. Among the guests present were Count Perera, Professor Benedett, Dr. Carlo Savini, Dr. R. F. Sheenan, Dr. Fenton B. Turck, Col. F. R. Keefer, U.S.A.; Dr. John A. McIsaacs, Dr. H. W. Frauenthal, Dr. Frank C. Lewis, Col. E. K. Sprague, U. S. Public Health Service; Dr. John Duff, and Dr. A. B. Hirsh.

Entrance Examinations for Public Health Service.—Examinations of candidates for entrance into the regular corps of the United States Public Health Service will be held on December 6, at Washington, D. C., Chicago, New Orleans and San Francisco.

Industrial Hygiene Course.—A course of lectures on industrial hygiene for nurses is being conducted by the School of Sociology and Social Service of Fordham University, New York City, each Thursday evening from 8 to 10 o'clock on the twenty-eighth floor of the Woolworth Building. The subjects discussed are public health, accident prevention, first aid, sanitation, workmen's compensation, protective legislation, child labor, continuation schools, industrial diseases, and general welfare work in industry.

Berlin Marriage Advice Bureau.—A few years ago Vienna opened a bureau for giving advice to those contemplating matrimony and those already involved in unfortunate unions. So great was the success of this bureau that Berlin has followed Vienna's example and opened a similar institution in the poorer quarters of the city in a modern former school building. Dr. F. K. Scheumann is head of the new bureau, and is quoted as stating as follows the aim of the institution: To serve as a guide, friend, and counsellor to three particular classes of human beings: those who stand expectant before love, those who stand uncertain before the dispensation of marriage, and those who are already involved in marriage. Their problems will be dealt with in a friendly manner from a scientific, medical, social and human viewpoint.

Gifts and Bequests.—Through the will of the late Louise H. Vanderbilt, wife of Frederick W. Vanderbilt, which was recently filed for probate, legacies of $10,000 each were bequeathed to the following institutions and organizations: the New York Orthopedic Dispensary and Hospital, the Woman's Hospital, the Children's Aid Society, the American Society for the Prevention of Cruelty to Animals, the Anthony Home, the Stanton Street Helping Hand Association, and the New York Women's League for Animals.

A gift of $25,000 from Hancke Hencken of New York City to the building fund of the new Lutheran Hospital was announced at a dinner of the hospital advisory committee held recently at the Hotel Astor. Henry Kroger, chairman of special gifts work in connection with the drive by the hospital for $750,000, announced the contribution, saying that Mr. Hencken, who is not officially connected with the hospital, had previously given $20,000 in support of its work. The drive to raise the remainder of the fund will be held from November 29th until December 10th.

Personal.—Dr. Stephen J. Spitzer has been appointed a surgeon in the Sydenham Hospital, New York City.

Among distinguished guests recently in the United States was Dr. P. Paru, who is regarded as one of India's greatest women physicians. She is associated with Dr. Anna Kugler in Guntur Lutheran Hospital.

Dr. John B. Byrnes, Jr., for a number of years associate obstetrician and gynecologist to Kings County Hospital and St. Peters Hospital, has been made manager of the Brooklyn State Hospital.

Dr. Roy E. Bushong, who has recently completed his fellowship training in extramural psychiatry with the National Committee for Mental Hygiene, New York City, has been appointed director of the mental hygiene clinic of Milwaukee County, Wisconsin.

Dr. Henry J. Gerstenberger, of Western Reserve University School of Medicine, and director of pediatrics at the Babies' and Children's Hospital at Cleveland, recently delivered an address on Studies in Rickets before the Section of Surgery of the Buffalo Academy of Medicine. Preceding the lecture, Dr. Gerstenberger was guest of honor at a dinner at the Hotel Statler, given by the Fellows and Associates of the Academy.

Dr. Janet G. Travell, who was graduated from the Cornell University Medical College in 1926, and who won the first of the John Metcalfe Polk Memorial Prizes for excellence in scholarship, has been made one of the medical staff of the New York Hospital, where she is the only woman physician.

Dr. J. F. Montague of New York addressed the Nassau County Medical Society Thursday evening, October 14, on the Rectal Diseases Amenable to Office Treatment.

Dr. Adolf Lorenz, of Vienna, expects to arrive in this country on November 21. He will resume the practice of orthopedic surgery at the office of Dexter D. Ashley, 346 Lexington Avenue, New York.

Society News and Notes.

At the International Physiological Congress held recently in Stockholm, the American Physiological Society tendered an invitation to the representatives of the various organizations to hold the next International Congress in the United States. This invitation was accepted by the bodies represented, and plans are being made for a meeting to be held in this country in 1929.

* * *

The Beth David Hospital Clinical Society elected the following officers at its recent meeting: Chairman, Dr. Jacob Sobel; vice-chairman, Dr. Marks S. Shaine; secretary treasurer, Dr. M. H. Levine.

* * *

An innovation in the way of animal welfare has recently been introduced in New York City by the Society for the Prevention of Cruelty to Animals in the form of a motor drinking tank. This tank holds 300 gallons, has two faucets to enable drivers to draw water in pails if they wish, and a bubbling cup for the use of humans. The society has announced that it expects in the near future to make all its drinking tanks movable by converting them into motor drawn receptacles.

Under the auspices of the *Internationale Gesellschaft für Sexualforschung* the International Congress on Sexology was held in October in Berlin. Among the subjects discussed wilth relation to their connection with sex problems and psychology were race, nationality, heredity, transformation of the sexes, rejuvenation, the psychology of sex and of the various life periods, intelligent choice of a mate, celibacy, illegitimacy, sex in art and religion, sexual crimes, eugenics, birth control and other problems. Among the speakers at the recent International Congress were Professor Steinach of Vienna, Dr. Harry Benjamin of New York City and Dr. Marinesco of Bucharest.

* * *

The National Association for Music in Hospitals, founded in 1925, has recently announced that it will offer scholarships to musicians willing to be trained in the work of making available suitable music for the sick. The association works in every way in conformation to hospitals conditions, standards and regulations, and cooperates closely with the institutional staff of doctors and nurses. One of the honorary vice presidents of the association is Dr. Frederick Peterson.

* * *

Dr. Robert Chambers, professor of microscopic anatomy at Cornell University Medical College, will deliver the second Harvey Society Lecture at the New York Academy of Medicine (new building, 103rd Street and Fifth Avenue), on Saturday, November 20, 1926. His subject will be The Nature of the Living Cell Revealed by Microdissection.

* * *

The first annual convention of the New England Association for Physical Therapeutics met in Boston, October 26th-28th. The association was founded in 1906. Among the speakers were Dr. Herman Goodman, Dr. Richard Kovacs and Dr. Wm. B. Snow of New York; Dr. H. V. Robinson of Montreal, Dr. William Martin of Atlantic City, and Dr. J. S. Stone of Boston, president of the Massachusetts State Medical Society.

* * *

The International Council for the Education of Exceptional Children held a convention recently at which the following were elected officers for the coming year: president, Elizabeth Farrell of New York City; secretary, Lavinia Warner of Ohio University; treasurer, Hanarose Haggerty, of Dubuque, Iowa.

* * *

The Nassau County Medical Society at its October meeting heard Dr. J. F. Montague of New York City speak on Rectal Diseases Amenable to Office Treatment.

* * *

The first meeting to be held by the New York Academy of Medicine in its new building, Fifth Avenue and 103rd Street, will be on Thursday evening, November 18, at 8:30 o'clock. This will be the occasion of the Wesley M. Carpenter lecture, which will be delivered by Prof. Michael I. Pupin of Columbia University on the subject, Ionization and Chemical Reactions.

The Section of Orthopedic Surgery of the New York Academy of Medicine will meet in the new building Friday evening, November 19, at 8:30. The chief feature will be the presentation of cases by Dr. Sigmund Epstein from the Bronx Hospital, Dr. P. William Nathan from the Mt. Sinai Hospital, Dr. A. DeF. Smith from the New York Orthopedic Hospital, Dr. Charles H. Jaeger and Dr. Walter I. Galland from the Lenox Hill Hospital, Dr. Reginald H. Sayre and Dr. L. T. LeWald from Bellevue Hospital, Dr. Percy W. Roberts from the Hospital for Ruptured and Crippled, Dr. Leo Mayer from the Hospital for Joint Dieeases, and Dr. Fred H. Albee from the Post Graduate Hospital. Other meetings will be as follows: Section of Laryngology and Rhinology, November 24, with the presentation of cases by Dr. David H. Jones and Dr. Irving W. Voorhees, and paper of the evening on Coagulation Time Prior to Tonsillectomy, by Dr. Westley M. Hunt; the Harvey Society, November 20, with a lecture by Prof. Robert Chambers of the Department of Microscopic Anatomy of Cornell University Medical College on the Nature of the Living Cell Revealed by Microdissection. The Academy has given special notice that all meetings announced will be held at Fifth Avenue and 103rd Street unless otherwise noted on the programs.

The Committee on Medical Education of the New York Academy of Medicine has just published a synopsis on Approved Opportunities for Graduate Study in Röntgenology in New York City. This synopsis is the last of a series of twelve covering dermatology and syphilology, obstetrics and gynecology, internal medicine, ophthalmology, otolaryngology, pediatrics, surgery, urology, neurology and psychiatry, orthopedic and rehabilitation surgery, röntgenology, and preclinical medical science subjects. Copies of the synopses may be obtained on application to the bureau of clinical information of the academy.

Book Reviews

ELECTROTHERAPY

Electrothermic Methods (Desiccation and Coagulation) in the Treatment of Neoplastic Diseases. Designed as a Practical Handbook of Surgical Electrotherapy for the Use of Practitioners and Students. By J. Douglas Morgan, B.A., M.D., Formerly Radiologist, Ross Pavilion, Royal Victoria Hospital, Montreal. Illustrated with thirty-six Line and Halftone Engravings. Philadelphia: F. A. Davis Company, Publishers, 1926. Pp. 172.

Surgery of Neoplastic Diseases by Electrothermic Methods. By George A. Wyeth, M.D., New York. Preface by Howard A. Kelly, M.D., Baltimore. With One Hundred and Thirty-seven Illustrations. New York: Paul B. Hoeber, 1926. Pp. xvi-298.

Now that electrodesiccation and electrocoagulation are being used by the general practitioner and much of the mystery surrounding electrothermic methods is being dispelled textbooks on the subject are beginning to appear. Such books are especially welcome because medical schools have not dignified the subject by giving courses therein. Morgan asserts that his little book is the first to be devoted exclusively to these methods. The purpose of the book is to supply to the medical profession a statement of the value of the electrothermic methods, the means of their production, and the manner of their application. Enough is shown to the inexperienced operator at least to make a beginning. After discussing the first principles and definitions of electricity and the chemical and physical effects of currents, surgical diathermy is taken up. In a general summary the technic and indications for the treatment are given in a direct, terse but complete manner. A chapter is also devoted to the value of the socalled endotherm or radioknife, which requires a special apparatus and technic. This is the very last word in electrothermic methods and is still in its early infancy. The illustrations are numerous and purposeful. Much information is included within the covers of this little book.

* * *

Howard A. Kelly, in his introduction to Wyeth's book, notes the following advantages for the treatment of accessible forms of malignancy with electrothermic methods: a shortening of the time of an operation, partly due to the absence of hemorrhage; there is no handling of tissues; operations can be done at one or more than one sitting; an infected field is often sterilized, leaving a clean wound; granulations form promptly and afford an excellent field for grafts; malignant disease can be sterilized and destroyed *in situ,* leaving a healthy slough; there is, as a rule, but little, or no after pain; the scar is less likely to pull and cause disfigurement; certain secreting or infected nonmalignant sacs or diverticula can be destroyed and left *in situ;* beautiful, delicate dissections can be effected with the needle—the acusector. The scalpel and ligature are discarded.

There is some confusion in the terminology and Wyeth suggests the use of the word endothermy to indicate the surgical application of high frequency currents, and the use of the word diathermy to indicate medical applications. After going into the history of high frequency currents, their production and effects on tissue are thoroughly discussed. The three modalities, monopolar endothermy, bipolar endothermy and the endotherm knife are then described in great detail. With the latter, a cutting current is developed by the three element vacuum tube and is of such extremely high frequency that it produces a molecular dissolution of the tissues, sealing lymphatics as it cuts by a thin line of coagulation. This appears to be the last word in the surgery of malignancies. The application of endothermy to lesions of the mucous membranes, including leucoplakia, epulis, ranula, tonsillectomy, larynx, rectum, hemorrhoids, uterus, urethra and vulva, and bladder and also to skin lesions is then described. There are numerous citations from other authors. The illustrations are very useful, including untouched, actual photographs of lesions before and after treatment, which are very convincing. Micropathology is not neglected. Both the author and the publisher are to be congratulated upon the publication of this pioneer work.

BIOLOGICAL EFFECT OF LIGHT

Biologische Lichtwirkungen beim gesunden und kranken Menschen unter besonderer Berücksichtigung der Rachitis. Eine Ubersichtsarbeit. Von Priv.-Doz. Dr. Fr. Peemöller. Leitender Arzt der Abteilung für physikalische Therapie des Allgemeinen Krankenhauses Hamburg-Eppendorf. Sonderabdruck aus der Strahlentherapie, Bd. XX (1925).

This is an exhaustive monograph on the biological effect of light in the healthy and diseased human being, especially in rachitis. The results with heliotherapy are discussed in detail, with special consideration of the effects of the different regions of the spectrum on rachitis. The rays are divided into visible rays, the dark heat rays, the ultraviolet rays and ultraviolet plus heat rays. The histology of the skin changes as shown by erythema and pigmentation is described. In addition the effect of the light upon the internal organs and their functions are taken up. The effects on the blood, circulation, respiration, metabolism, enzymes, toxins and antibodies, and the nervous system and smooth muscles are given in detail. A very extensive bibliography of the German literature is appended, but very little attention is paid to publications in other languages.

OBESITY

Obesity. By Leonard Williams, M.D. Oxford Medical Publications. London, New York, etc.: Humphrey Milford, Oxford University Press, 1926. Pp. ix-171.

This monograph differs markedly from the usual in that it is written and conceived in somewhat of a whimsical style. While it gives due consideration to the modern views as to the endocrinological factors of obesity and vitamines, the author has drawn much assistance from Francis Heckel's *Les Grandes et Petites Obésités* and inspiration and stimulation from two works by William Wadd, entitled *Cursory Remarks on Corpulency,* published in 1819, and *Comments on Corpulency,* published in 1829, both rare publications. Some of the illustrations are drawn from these works, while others are original or drawn by Stampa who is an artist for *Punch,* the comic paper.

There are five chapters, entitled The Tributaries

of Obesity, The Bantlings of Obesity, Eve, dealing with obesity in the female, The Complicity of the Endocrines, and Counterchecks. Even these titles are out of the ordinary. There are five appendices, dealing with a table for average weights for men and women, respectively, average weights and heights in the young, the modified Banting dietary, and the unfired dietary.

The material proves most interesting reading, being both instructive and a source of extreme pleasure. One is really surprised that a medical publication can afford so much satisfaction and pleasure. It is most admirably suited for reading in leisure hours.

DIABETES

The Pathology and Treatment of Diabetes Mellitus. By George Graham, M.A., M.D., F.R.C.P., Assistant Physician, St. Bartholomew's Hospital. Oxford Medical Publications. Second Edition. London, New York, etc.: Humphrey Milford, Oxford University Press, 1926. Pp. xv-230.

The discovery of insulin has necessitated a second edition of this little book to keep it abreast of the times. Many alterations have been made in the text, and a new chapter on the special properties of insulin and another giving the details of the treatment with insulin have been added. Part I refers to the physiology of sugar metabolism and also includes the chapter on insulin. Part II refers to the different types of diabetes mellitus and the methods of distinguishing them, the different theories of the cause of diabetes, the principles of treatment and the principles and details of the insulin treatment. Also a chapter on the causation and treatment of diabetic coma. Eight appendices contain some valuable practical material, such as the ladder diet of the Medical Clinic of St. Bartholomew's Hospital, the maintenance diet, recipes, food values, the metabolism and growth from birth to puberty, the necessary clinical methods of examining urine and blood, basal metabolism, and charts for gauging the correct dose of insulin. On the whole this is a very valuable little book.

GUIDE FOR DIABETICS

A Guide for Diabetics. By Walter R. Campbell, M.A., M.D. (Tor.), Department of Medicine, University of Toronto and Toronto General Hospital, and Mame T. Porter, B.Sc., Dietitian, Toronto General Hospital. Baltimore: The Williams & Wilkins Company, 1926. Pp. 259.

Since the successful treatment of diabetes mellitus hinges upon the proper management of the patient's diet it is absolutely necessary that the patient should have accurate knowledge as to the nature and quantity of his food, as well as to note the progress of his condition. The disease is such that the constant supervision of the patient by the physician is necessary. The purpose of this guide is to explain certain facts about diabetes and to provide him with a number of tested recipes for suitable foods. Particular attention is paid to the arrangement of suitable menus, which the patient must work out for himself. A blank page is inserted, which is to serve the purpose of recording the patient's questions and the proper answers. Additional recipes may also be added. The material presented has been used by the authors in mimeographed form for the instruction of their patients. The special diets have been arranged with a view to relieving the monotony of the diet and the satiety of the patient's appetite. A table of equivalents is also given for foods having the same food value as the original food for which they may be substituted, thus providing a wide variety of choice.

After discussing the nature and cause of diabetes, with the objects of treatment, the food principles and the use of food, the dietetic treatment in general is taken up. The administration of insulin with its dangers is described. The other subjects discussed include ketosis, acidosis and coma, body weight, infections, hygiene, traveling, uranalysis and the blood sugar. There is given a very extensive table of food analyses and also directions for home canning. This guide ought to prove very valuable to every diabetic patient.

FOCAL INFECTION

Why Infections? In Teeth, Tonsils and Other Organs. By Nicholas Kopeloff, Ph.D., Associate in Bacteriology, Psychiatric Institute, Ward's Island. New York & London: Alfred A. Knopf, 1926. Pp. xi-182.

This is a treatise on focal infection and apparently intended for the laity. It enumerates the sources of focal infection as found in the teeth, tonsils, nose, throat and sinuses, the ears, eyes, digestive tract, kidneys and bladder, and in the male and female genital passages. It is well written, in an interesting style that will captivate the reader, and the facts are well presented, even though the book is not written by a physician. It may well and unhesitatingly be recommended to the laity and even the medical student will find much of value in it.

THE NEW NATIONAL FORMULARY

The National Formulary. Fifth Edition. By Authority of the American Pharmaceutical Association. Preferred by the Committee on National Formulary of the American Pharmacutical Association. Published by the Association, 1926.

The National Formulary fills an important place in the field of what might be termed practical materia medica, for in its pages will be found approved formulas for many of the elixirs, syrups and solutions to which the physician is so apt to turn when confronted with problems of what to prescribe. The constant increase in the demands on the time of the medical student in the efforts of the teachers to keep the curriculum abreast of medical progress has resulted in an abbreviation of the time devoted to materia medica. As a consequence the young practitioner of today is frequently not so well informed in this field as was the graduate of fifty years ago. The wave of therapeutic nihilism, which, arising in Vienna, swept over the medical world, shows some indications of recession. There are signs of a somewhat more respectful attitude toward this branch of medicine of late years and the *National Formulary* offers assistance to the physician who wishes to make use of the modern materia medica but is not sure of his own ability to write a prescription which will not involve incompatibilities. A tremendous amount of conscientious work has been done by the committee which prepared the volume and this work is here made available to the physician at a comparatively slight cost.

This edition contains 549 formulas and sixteen descriptive chapters or paragraphs in Part I, while 188 articles are listed and described in Part II. The number of formulas given has been decreased by

thirty-five, while twenty-five more articles are listed than appeared in the fourth edition. This increase is due to the large number of deletions from the U. S. P. IX, the rule having been followed of listing in the *National Formulary,* for a time at least, all articles deleted from the *Pharmacopœia.*

Part III of the work contains detailed directions for various tests for identity and purity and for making those stains, reagents, culture media, etc., which are so important to the laboratory worker. In this part will also be found a number of tables, which will be of special interest to the manufacturing pharmacist, such as the percentage of alcohol which should be present in finished tinctures, fluid extracts, etc.

The book is well made, is well edited, and reflects great credit upon the committee and upon the publishers.

EUTHANASIA AND THE NOVELIST

Sorrell and Son. By Warwick Deeping. New York: Alfred Knopf, 1926.

In *Sorrell and Son,* a novel of the hour, the hero, a surgeon, caused the painless death of his own father, who is suffering from hepatic cancer. The fact is set forth as the praiseworthy performance of a filial duty by a son peculiarly attached to his father. The act is so out of keeping with the character of the young surgeon and so much at variance with the fundamental attitude of the medical profession that it mars an otherwise excellent and well presented novel. Had the young surgeon merely continued the administration of morphine in sufficient doses to insure relief from pain until such time as death came the story would have lacked in dramatic climax, but it would have been more true to medical tradition and more in keeping with his character.

The failure of the author to differentiate between the causing of death to be painless and the causing of painless death is another instance of the popular misconception of what is really meant by euthanasia, though that term is not used in the book. Under no circumstance is the surgeon justified in deliberately causing death. That is the basic attitude of the medical profession and one supported by popular approval. But where death is inevitable the surgeon is justified in making that death painless.

Edith Wharton, in *The Fruit of the Tree,* published some years ago, had a trained nurse deliberately administer an overdose of a narcotic, thus hastening the death of a chronic sufferer. This act was condoned by the author as justifiable, but the medical profession did not take that view, nor should it. That the surgeon is justified in diminishing the horrors of death by the administration of narcotics is admitted by all, but this does not mean that he may wilfully hasten death by the administration of an overdose of the narcotic.

Euthanasia is popularly defined as a happy death or a desirable death. The physician may do all in his power to diminish the frightfulness of the inevitable but must not hasten it. Aside from the contravention of medical tradition, the author has written a strong work which will be of special interest to physicians because it tells in detail of the education and training of a surgeon in London. The story of his education takes him through Cambridge and eventually London University.

There are several well drawn pictures of the operating room, accurate, dramatic, but not too detailed. One of these describes the first important operation performed by the young surgeon without supervision and another describes his first operation before the class. This was for a papilloma of the bladder. "A white blade drew a steady line that grew red upon the pale abdomen. The incision deepened, swabs were at work, retractors; forceps were clipped on; the unconscious and gently palpitating figure seemed surrounded by grave and interested faces and calm purposeful hands."

One wonders if the story accurately presents the social conditions of the time and place. The young heroine gives herself to her lover but declines marriage with him as tying her down so as to interfere with her career. The hero has previously had an affair with another girl, who goes into it quite deliberately without expectation of marriage. Another couple live together as lovers long before being married. It reads rather like Paris than London in this respect. The author suffers from a mild Americanophobia which manifests itself in occasional slurring references to Americans, but where he quotes an Americanism he misquotes, saying "Sick in the stomach" instead of "sick at the stomach."

Stephen Sorrell, the father, is an interesting and well drawn character, whose life is devoted to giving his son, the surgeon, his chance in life. The book makes interesting reading.

Medicoliterary Notes.

During the year 1925, the International Health Board of the Rockefeller Foundation has, according to its recently published Twelfth Annual Report, given assistance to public health enterprises in ninety-seven states and countries. It participated in infection and sanitation surveys, operations for the control of yellow fever and hookworm disease, field studies and experiments in malaria control, county and rural health work, the development of special divisions of public health services, and the establishment and maintenance of schools and institutes of hygiene and public health. It also provided 197 fellowships for training in public health for men and women from twenty-seven countries, supported field stations for the training of prospective health officers in methods of malaria and hookworm control and in other public health work, and contributed funds to the Health Section of the League of Nations toward the support of international interchanges of public health personnel, the maintenance of epidemiological and public health intelligence service, and the training of government health officials in vital and public health statistics.

* * *

The Natural History Division of the British Museum in London has recently installed a small but interesting collection of models of disease bearing insects, including malaria, yellow fever and other mosquitos, the midge carrier of the sandfly fever, a small West African horsefly conveying Calabar swelling, two kinds of tsetse flies which carry the parasites causing trypanosomiasis and nagana, the house fly, plaque flea, body louse, two forms of ticks, and the itch mite.

* * *

The municipal court of Berlin has recommended that a law be passed making it illegal for orchestras and other forms of music, including the radio, to continue playing in public places of entertainment after a comparatively early hour. The court declares that, under the exhilaration of music, the guests in cafés, restaurants and theatres drink alcoholic concoctions to excess. By the police closing hour, 1 a. m., the guests are in a quarrelsome mood, and argue loudly either with friends or other groups on the street, to

the detrimental disturbance of those who wish to sleep, whose health consequently suffers. The recommendation closes by saying that the court therefore decides it is necessary to order the curfew rung at an early hour on all forms of music, and, since liquor without music does not produce brawls, the hours during which liquor may be sold are not cut down.

* * *

Prof. Louise Pound of the University of Nebraska has recently published a report of a speech study she has made which brought to light the fact that the word *yes* is fading out from the English language. A canvas of substitutes for it among a large group of young persons produced "all right," "you bet," "O. K.," and the various nasal sounds, such as "uh-huh," etc.

* * *

It is related that George Bernard Shaw, a few days after his seventieth birthday, was roped into a drawing room party of a rather highbrow nature, at which the special attraction was a violinist. Said the hostess to Mr. Shaw, after the violinist had rendered one or two numbers: "Well, Mr. Shaw, what do you think of my discovery?" Replied Mr. Shaw: "I find in him a great resemblance to Paderewski." A painful pause. Then, "But, Mr. Shaw, Paderewski is not a violinist." "Exactly!" snapped G. B. S.—*New Yorker.*

* * *

There are no polar bears or other animal life in the South Pole region, according to a recent statement attributed to the explorer, Stefansson.

* * *

Don't Stop Until It's Tried: the Facts About Prohibition, is the title of a recently published book by Irving Fisher (Macmillan). Mr. Fisher has come to the conclusion, apparently rather reluctantly, that prohibition is the best available solution of the socalled "drink problem."

* * *

That women can work faster and often more accurately than men, but that men have better powers of judgment, is stated as the result of a series of experiments recently made by Isabel Stewart at the Psychological Laboratory of Johns Hopkins University. Similar tests were given to school children, and the girls found superior to the boys in speed and accuracy of performance, but the boys outdid them in judging weights and distances.

* * *

Another biography of Edgar Allan Poe, this time in two volumes, is a late publication of Doran. The author is Mary E. Phillips, who is said to have been working for twelve years on the book. Her search for material has covered every community in which Poe passed any time, not only in this country, but in England and Scotland. It is asserted that sixty-five per cent. of the contents of the work are here presented for the first time, and include many letters, records, documents and illustrations never before published.

* * *

In a survey of caterpillars of the region, Dr. George E. Beyer of the Louisiana State Board of Health states that the most poisonous variety is the larva of the southern flannel moth and its northern variety. Some of the spines of this species are hollow and connected with a poison secreting cell, the toxic effect of which is exceedingly virulent. Accidental contact with this caterpillar by a human being may, according to Dr. Beyer, bring about numbness, pain and nausea.

* * *

The lowly dachshund, banned from England during the World War, is once more in style, the London press reports. Dachshunds are being imported from Germany in such numbers that the craze threatens to eclipse the popularity of the police dogs or Alsatians.

* * *

A new and enlarged edition of Jeannette Mark's book entitled *Genius and Disaster* has been issued by the Adelphi Company. Another similar work of recent date is Arthur Jacobson's *Revaluations: New Studies in Genius.*

* * *

Dr. Charles Sheard of the Mayo Clinic, Rochester, Minn., has recently made public, according to the *Science News Letter,* a bloodless way of finding out what is going on in the bloodstream. The eye is a poor instrument for analyzing color, says Dr. Sheard. The eye can estimate the color in the skin itself, but there is also the color contributed by the blood, which is reflected by tiny capillaries in the skin surface. The only scientific method of finding out the rôle played by pigment and blood in the color of the skin is to use a color analyzing instrument. An accurate method of determining the color of the ingredients of the skin is expected to be of value in indicating the condition of the blood in cases of anemia, jaundice, Addison's disease, and in various diseases in which the skin turns bluish for lack of oxygen in the blood.

* * *

Some Eskimos are the possessors of as many as twenty different names, says the *Science News Letter.*

* * *

Curiosity on the part of the police of the Free Port of Hamburg as to why the Chinese should buy their tombstones in Budapest led to the discovery of an attempt to smuggle more than two hundred pounds of pure heroin through the German port to Shanghai, according to a report to the *New York Times.* Metal boxes containing the drug were painted white and arranged in a mosaic forming fanciful gravestones. One policeman, however, had travelled in the Orient, and he felt that either the styles in tombstones had changed recently in China or the present shipment was a fake. Upon the discovery of the drug mosaic, the police put out a drag net and into it fell a man, claiming to be an American named James Dolan. His association with questionable characters and his lavish mode of life directed suspicion against him and he was arrested. The police wired to a number of European capitals the names and descriptions of others they believed to be leaders in an international drug ring.

* * *

One of the significant books of the summer was Dr. George W. Crile's *A Bipolar Theory of Living Processes,* published by Macmillan.

* * *

At the recent convention of the American Gas Association held at Atlantic City, a report was read giving the results of a questionnaire that had been previously sent out by the association, in an endeavor to discover the most popular national dishes. These proved to be pie and angel cake. Missouri proved to be partial to all kinds of Spanish concoctions, New York loves pie and cake, and New Jersey was not able to decide on its favorite dish.

* * *

New York City could do well to imitate Paris in an attempt to check the nuisance of the much used taxi horn. After a careful study of the situation, M. Morain, the Prefect of the Police, has brought about the passage of an ordinance which makes illegal the use of any but "a horn sonorous, uniform, and producing a sound low in the scale, which it will be forbidden to repeat." Many of the citizens of Paris have heartily approved the prefect's attitude and efforts, and are cooperating with him in the attempt to do away with the nuisance, which is also a menace to health.

* * *

Recent publications of interest to the medical profession include: *Alcohol and Longevity,* by Raymond Pearl, Ph.D. (Knopf); *A Psychological Study of Cancer,* by Elida Evans (Dodd, Mead); *Mental Tests,* by Frank N. Freeman (Houghton, Mifflin); *Social Anthropology,* by Geza Roheim (Boni & Liveright); *Essays in the History of Medicine,* by Dr. Karl Sudhoff (Medical Life Press); *Delusion and Belief,* by Dr. C. MacFie Campbell (Harvard University Press); *Industrial Diseases;* Rapid Reference Manual, especially arranged for the use of the medical profession in New York State by Dr. C. T. Graham-Rogers, Medical Inspector of Factories, and published by the Division of Industrial Hygiene of the New York State Department of Labor; *Delinquents and Criminals,* by Dr. William Healy and Augusta F. Bronner, Ph.D. (Macmillan); and the novel, *Our Doctors,* by Maurice Duplay, translated from the French by Dr. Joseph Collins.

* * *

Dr. Rosenbach, of Philadelphia, recently purchased at the Britwell Court Library sales in London five copies of *The Treasure of Poore Men,* each of a different edition, all in black letter and all printed before 1550. The work is a collection of medical recipes. The aggregate sum paid was £695. All are quite rare; less than a dozen copies of the work are in existence.

Abstracts from Current Literature

PHYSIOTHERAPY

Ultraviolet Ray Therapy in Tuberculosis of Children.—Joseph H. Marcus (*Archives of Pediatrics,* June, 1926) summarizes his experience in treating tuberculosis in children as follows:

The glandular type of tuberculosis, especially cervical, bronchial, and mesenteric, are amenable to treatment, the results obtained ranging from fair to excellent. In the latent pulmonary type, the improvement noted was a resultant increase in weight accompanied by a state of euphoria. The existent pathology was not influenced, as checked up by physical examinations and röntgenographic interpretations. Ultraviolet ray therapy, while not specific, is the most valuable recent contribution to the treatment of certain types of tuberculosis, and should not be used as a distinct and separate entity. It is the duty of the physician to educate the people to the new knowledge of sunlight, both natural and artificial, as a means of health, that it is a stimulant, a tonic and nature's universal disinfectant.

Method of Treating Asthma by Radiation.—S. Gilbert Scott (*British Medical Journal,* June 5, 1926) has no new theories as to the causation of asthma, but the results obtained from the method described leads him to believe that the primary cause will eventually be found to be metabolic, with or without some local irritation reflex. He believes the influence of radiation on asthma to be complex, and that it is not a direct influence on lung tissue, but some profound indirect or secondary change affecting the whole body.

The technic includes the following factors: The dose is 10 through 3 mm. aluminium; a low voltage; a large radiation field. This dose is administered once a week to the average case—twice a week if the case is severe. After the fourth dose an interval of two weeks is allowed, then it is repeated once a month for four months; after that the patient is instructed to come up as soon as any wheezing or "tightness" of the chest is noticed, when a further dose is given.

The immediate effects are experienced within a few hours of the treatment: tightness of the chest is relieved first, followed in twenty-four hours by an increase in the phlegm. With the small dose no nausea is experienced. All the patients treated obtained definite relief. No blood changes were noted. The number of treatments necessary to get rid of the wheezing varied.

A New Development in Radium Therapy: The Application of the Later Disintegration Products of Radium to the Treatment of Certain Skin Conditions.—John P. McHutchison and W. Herbert Brown (*Lancet,* April 10, 1926) report the use of radioelements, radium D and radium E, which were extracted from used radium emanation tubes, and in equilibrium together were prepared for medical use in the form of applicators of different kinds. Such applicators have been found to exert a beneficial action in the treatment of lupus erythematosus and of various types of nevi. Conditions like eczema and psoriasis will also respond, but it has not been found convenient to treat large affected areas by means of applicators.

The radiation from radium D and radium E has the unique property so far as radium treatment of skin conditions is concerned, that it is all absorbed by the part being treated, since its effective penetration is only about 3 mm. of tissue. Radium D and E applicators retain their strength and may be used for many years; sixteen years elapse before the activity declines to one half of its original value.

Radiotherapy in the Flajani-Basedow Disease.—E. Milani pronounces radiotherapy (*Revue Française d'Endocrinologie,* February, 1926) a little known method of treating this disease, but nevertheless a method of precision and comparable in its results with the most favorable surgical statistics. He himself reports 1080 cases treated by radiotherapy, presenting only sixteen per cent. of failures and seven per cent. of recurrences. The principal indication for its use is in early and primary cases. The results are less satisfactory in Basedowified goitre, and it is contraindicated in cases of irregular form and in stenotic goitre. The nervous, vasomotor, and secretory symptoms first show improvement, together with metabolic and blood changes. While tachycardia and tremor are easily relieved, the goitre and exophthalmos are far more rebellious. The dose cannot be stated mathematically. Small doses are always stimulating and find little application here. Biological tests should be employed to estimate the degree of improvement.

In discussing the paper, N. Pende insisted on the nature of Basedow's disease as an endocrine sympathetic syndrome. Surgical intervention appears to him ineffective, because directed against the thyroid alone. By exclusive medical treatment he has obtained excellent results in 167 patients. The full treatment consists in combining psychotherapy, a diet of fats and carbohydrates, radiotherapy, and mixed organotherapy.

Röntgenographic Diagnosis in Gynecology.—I. F. Stein (*Surgery, Gynecology and Obstetrics,* 42:1) states that röntgenography after gas inflation of the abdomen is of material aid in diagnosis. In obèse, uncooperative, ignorant, or mentally deficient women it may be the only means of accurate diagnosis before operation. Its value lies not alone in positive evidence but also negatively in allaying suspicion of pregnancy or pelvic lesions with few palpatory findings. As a matter of record it has great value. By a careful technic the uterus, ovaries and falloppian tubes, round ligaments, and bladder can be clearly depicted on the x ray film, after surrounding the viscera with gas. Tumors are thus readily differentiated.

Carbon dioxide is preferred to air or oxygen because of more rapid absorption. All three gases are safe. The transuterine route is preferable when the Rubin test proves the tubes permeable. The latter procedure is of distinct value in sterility both diagnostically and therapeutically.

Treatment of Rodent Ulcers by Radiation.—R. W. Lewis (*Annals of Surgery,* Vol. 74:2) asserts that: radiation treatment of basal cell epitheliomata is an excellent method because of its absence of operative procedure, its simplicity, excellent cosmetic results, and high percentage of permanent cures. Statistically, there is little difference in the ultimate results between treatment by radium and that by surgical excision. The treatment by radiation of those lesions where bone or cartilage is involved, or where the lesion is four cm. in diameter, or larger, is inadvisable. Treatment by radium should be undertaken in these conditions only when a surgeon, skilled in the treatment of cancer, finds the patient, for any reason, unsuitable for operation. The patient's risk, in treating, through mistaken diagnosis, a squamous epithelioma, is probably little, if any, increased, if the rule be observed to refer promptly for surgical removal any lesion which increases in size after radiation, or any lesion which does not respond immediately and strikingly to one or two doses of radiation.

Clinical Application of Ultraviolet Light.—Edwin T. Wyman (*Boston Medical and Surgical Journal,* August 26, 1926) says that the quartz lamp can be used as a substitute for sunlight and has the advantage of being available regardless of sunshine and weather. It can be given indoors so as not to subject the infant or child to the cold, and the doses can be more accurately gauged. There is, however, a very real danger of becoming too enthusiastic about ultraviolet therapy rays lest this form of treatment be looked upon by the physician and his patient as a quick and sure cure for all ailments. It can be said, however, that ultraviolet light therapy has a specific action in treating rickets and spasmophilia and is a valuable therapeutic agent in the treatment of tuberculosis of the mesenteric and bronchial glands and tuberculous peritonitis. Further investigations will be required in other fields before definite conclusions can be drawn.

The Present Status of Radiation Therapy in Carcinoma.—George W. Holmes (*Boston Medical and Surgical Journal,* August 26, 1926) maintains that each case should be carefully studied and a definite plan of treatment decided upon before starting any single form of therapy. Most curable cases are better treated surgically, but the surgeon should not attempt a radical cure where complete removal of the tumor is impossible. These cases are better treated by radiation alone. Preoperative rediation properly used probably increases the chance of surgical cure. Postoperative radiation has failed to prevent recurrence, and when prolonged

has caused permanent damage to the skin. In the treatment of recurrent and inoperable cases, relief of distressing symptoms should be the main object of the treatment. It is usually inadvisable to use heavy or prolonged doses in an attempt to cure.

Steam Cautery.—H. S. Souttar (*Lancet,* April 17, 1926) found that results similar to those obtained by diathermy can be obtained in a much simpler manner by the slow penetration of heat from a cautery maintained at a low temperature, and this is very conveniently done by a current of dry steam. The author has constructed an apparatus the applicator of which is maintained constantly at a temperature closely approximating to 100° C. The applicators vary in size from small points up to metal discs three inches or more in diameter.

So long as the applicator is kept in contact with the tissues heat slowly penetrates and produces coagulation, the depth of penetration for any one applicator being simply a function of the time and of the permeability of the tissues. With the large applicators and on moist tissues penetration takes place at the rate of about one inch in ten minutes. In contrast to diathermy very large applicators may be used, the rate of penetration being slightly greater with large applicators than with small ones. The author thinks that this is the most potent appliance available at present for dealing with large masses inoperable growth. The rate at which great masses of fungating carcinoma coagulate and disintegrate before it is astonishing, and yet in the end dense coagulum is left which gives complete protection to the deep tissues and allows time for their recovery, for the closure of large vessels, and for the formation of granulation tissue. Small superficial growths and ulcers can also be treated with certainty and yet without risk to the underlying deep structures. This treatment is especially applicable to epithelioma of the skin, particularly where this arises on a scarred surface, as after the treatment of lupus and similar conditions by x rays.

SURGERY

Plastic Surgery of Upper Lip and Nose.—V. P. Blair (*Surgery, Gynecology and Obstetrics,* 42:1) presents several illustrated cases in which he has met with creditable success by using the following plans to build up the bone about the orifice of the anterior nares: The implantation of cartilage; the use of a dental prosthesis after the soft tissues have been liberated from the periosteum of the maxillary bone and the sulcus has been lined with Thiersch grafts; the cheeks have been liberated from the maxillas and sutured in a forward position; and the lining of the nasal tube has been lengthened with a flap from the forehead, arm, or the mucosa of the mouth. The soft tissues have been drawn forward and suspended in this position, either by the implantation of cartilage or bone between the skin and framework of the dorsum of the nose, or by suturing the liberated columella in a forward position on the lower border of the septum.

There is a type of retracted nose in which the septum and the columella are both short, part of the cartilage of the latter being buried in the lip. The columella is also short in the complete double congenital cleft of lip and palate. In these cases the columella will have to be lengthened in order to bring the nose forward. In some cases the external nose was so small that it was necessary to piece out the covering as well as the lining in order to obtain a desirable result.

Perineal Excision in Cancer of Rectum.—J. P. Lockhart-Mummery (*British Journal of Surgery,* 14:53) presents a tabulated report on two hundred cases, showing that when the operation is performed under the most favorable conditions the mortality is only three per cent., and that the percentage of cures on a five year basis is fifty per cent.; while where specially favorable picked cases alone are dealt with the proportion of cures on a five year basis reaches the very high figure of seventy-three per cent. The operation is briefly outlined as follows:

The operation is done in two stages, a permanent colostomy being performed either a week beforehand or at the time of the resection. Either spinal or regional anesthesia is used, aided by gas and oxygen or twilight sleep. The patient is placed in the semiprone position, head down, and if a male a catheter is tied into the bladder. The anus is first closed with a purse string suture passed subcutaneously with a curved needle, and an incision is made from the base of the sacrum, passing around the anus and about one inch from it. The coccyx is removed by dissection, and the deep fascia divided transversely just in front of the sacrum. Both levatores ani muscles are divided close to the pelvic wall with scissors, and the rectum is then dissected off the vagina in the female, or from the urethra and prostate in the male, until the peritoneum is reached. The peritoneum is opened, and as much bowel drawn down as possible. The mesorectum is clamped off as far back as can be managed, and divided. The clamps are tied off, and, after dividing the peritoneal coat of the pelvic colon and stripping it back for a short distance, the bowel is crushed and divided with a cautery. The stump is ligatured and turned in with a purse string suture, and the wound in the peritoneum closed with catgut stitches. The wound itself is closed without drainage in most cases. In a few a small rubber wick is inserted. The wound is not dressed for forty-eight hours, and then the blades of a pair of dressing forceps are introduced between two of the stitches, and any accumulated fluid allowed to escape. If the wound remains quite clean, it is allowed to heal by first intention; but if the accumulation of serum continues, a stitch is removed, a small piece of drainage tube is introduced, and the cavity kept irrigated with weak Dakin or Milton solution. The patient is allowed out of bed on the fourteenth day, and is generally able to return home in from three weeks to a month.

The Influence of the Vermiform Appendix on Gynecological Surgery.—R. S. Statham (*British Medical Journal,* May 8 and 15, 1926) concludes that the appendix is very likely to be affected by pelvic inflammations and may be the cause of salpingooophoritis and its consequences more frequently than is expected. The appendix should be suspected and examined in all cases of pelvic peritonitis, and it should be removed if it is in any way diseased, to prevent further trouble at a later date. Even when the operation is performed for a condition which is not inflammatory the appendix should be examined; twenty per cent. of the author's series show definite disease of this organ, and two out of thirty-one appendices removed were reported as malignant. Acute pyosalpinx is frequently complicated by acute appendicitis and vice versa. Oophoritis as a disease, and apart from pelvic peritonitis, should not be diagnosed. If at operation the ovaries are found to be merely enlarged and not adherent, then the appendix is most likely to be the cause of the patient's pelvic pain. In corroboration of this, the number of oophorectomies performed at the Royal Infirmary has fallen to a quarter of the number which were done before the World War, and the results as to the cure of chronic pain have very greatly improved. The author advances with great diffidence that it is just as well to remove a pelvic appendix whenever found, even if it appears quite healthy to the eye.

Surgery of the Gallbladder.—W. J. Mayo (*Surgery, Gynecology and Obstetrics,* 43:6) states that in the Clinic cholecystectomy is performed in more than ninety per cent. of cases of ballbladder disease as against cholecystostomy in less than ten per cent. In average cases, if cholecystectomy can be performed as safely as cholecystostomy, it brings about permanent cure in a much higher percentage.

It should be remembered that after cholecystostomy the gallbladder becomes fixed in adhesions, and the mere absence of symptoms is no indication that it is functioning. Of the patients for whom we perform cholecystostomy rather than cholecystectomy, we expect a certain number will later require removal of the gallbladder.

In cases of acute cholecystitis, when the gallbladder is very large, distended and edematous, with localized peritonitis from complete blockage at the cystic duct, the author says he has had the best results from direct dissection of the cystic duct at the common duct, early closure of the cystic duct with a pair of forceps, and removal of the entire gallbladder, which is easily enucleated with its contained stones and septic material.

When there are stones to be removed from the common duct in the presence of jaundice, it is not wise to remove the gallbladder at the same time if removal can be avoided.

Accidents in performing cholecystectomy are most often due to insufficient care in locating and isolating the cystic duct and the cystic artery. It should not be forgotten that the cystic duct has is origin to the liver side of the pelvis of the gallbladder and that the cystic artery usually has its position to the inner side of the duct. Adhesions between the pelvis of the gallbladder and the common duct may drag the latter upward so that it may be mistaken for the

cystic duct, and in the course of operation a piece may be removed accidentally from the common duct. Again, if the cystic artery escapes and retracts deeply, in the attempts of the operator to catch it quickly with rat tooth forceps, the latter may bite a piece out of the hepatic duct, leaving permanent biliary obstruction, the repair of which is one of the most difficult problems in surgery.

The incision we use is based on that of Bevan, beginning as high as possible between the ensiform cartilage and the costal margin and passing down about two centimetres to the right of the median line, and of sufficient length to enable easy manipulation and also to permit the examination of the appendix and its removal if necessary. The reason this incision is advisable is that the common duct in its preduodenal portion is nearly transverse, but on passing under the duodenum into or behind the head of the pancreas it descends almost parallel to the long axis of the body close to the median line of the body. In the male, the distended gallbladder usually extends downward and to the right toward the anterior superior spine of the ilium; in the female, it more often extends toward the umbilicus and to the median line.

The author says he has found very helpful the suggestion made by L. L. McArthur some years ago to leave the peritoneum and the posterior aponeurosis of the rectus muscle uncut in the lower one fourth of the incision. These tissues can be retracted readily, and protect the lower part of the wound against hernia. Whereas hernia frequently used to follow operation on the gallbladder, he had seen none in the lower part of the incision since he had followed this practice. The liver usually comes down under the upper part of the incision, so that only a small space is unprotected.

Operative Treatment of Thenar Paralysis.—H. H. M. Lyle (*Annals of Surgery,* 84:2) offers a technic which attempts to combine the advantage of Steindler's flexor plasty combine the advantage of Steindler's flexor plasty with the good points of Ney's operation, as follows:

1. An incision is made over the extensor brevis pollicis extending from its insertion to a point where this tendon emerges from the posterior annular ligament, the tendon of the extensor brevis pollicis is then divided at this level. An anterior incision exposing the flexor carpii radialis at the wrist is made, the subcutaneous tissue is tunneled obliquely from the distal edge of the anterior annular ligament to the insertion of the extensor brevis pollicis and the cut end of the extensor brevis pollicis threaded through this tunnel, passed under the annular ligament and sutured to the tendon of the flexor carpii radialis above the annular ligament. The pulmaris longus, if present and sufficiently developed can be employed instead of the flexor carpii radialis.

2. Flexor plasty. A palmar lateral incision is made over the tendon sheath of the flexor longus pollicis, exposing it from its insertion to a point just below the head of the first metacarpal. The tendon sheath is opened and the tendon split longitudinally, the outer half is freed from its insertion and withdrawn from the sheath, the sheath is then closed over the internal half. The external half is carried subcutaneously around the outer side of the base of the first phalanx and sutured. This can be readily done as the previously performed incision for the exposure of the insertion of the extensor brevis pollicis gives an excellent exposure for the flexor anchorage. The thumb is then placed in the functionating position and fixed in plaster. Gentle active movement is begun on the twelfth day; all support removed on the twenty-first day.

The author reserves his operation for the cases in which it is essential to have a powerful pincer action. In the ordinary case he employs the simpler methods of Steindler or Ney.

Short Mesocolon in Gastric Surgery.—F. S. Mathews (*Annals of Surgery,* 84:2) describes four cases in which his procedure was either anterior or posterior gastroenterostomy using a considerable loop of jejunum above the anastomosis and in each case but one an enteroanastomosis was added to avoid the possibility of retention of intestinal contents in the segment of bowel above the gastroenterostomy. Following the operation there was no suggestion of vicious circle in any of the four and the patient in whom no enteroanastomosis was made has done quite as well as the others. Nevertheless an enteroanastomosis is an added security when a long loop has to be used.

When one encounters a case of very short transverse mesocolon, it will probably not be discovered until the work on the stomach has been completed. Then when the omentum is lifted up with the expectation of drawing the transverse colon immediately into the wound, one sees instead the large expanse of the posterior wall of the stomach covered only by a single leaf of the omentum. Posterior or anterior operation can easily be done. The posterior one would seem to be more desirable, especially if the omentum is of considerable size. But whether posterior or anterior operation is employed, a short loop of small bowel would seem undesirable because of the possibility of its being compressed by the descending colon. The question of whether the enteroanastomosis should be added may seem a debatable one. It has always been added in carcinoma cases where an anterior gastroenterostomy had to be made high on the stomach wall. The enteroanastomosis whether by suture or Murphy button adds very little to the length of operation and may be the means of sparing the patient a second operation.

Importance of Hematology in Surgery.—A. Piney (*British Journal of Surgery,* 14:53) lays down the following rules as indications which will correspond accurately in almost every case to the course of an infective process:

1. Slight neutrophilia with very little nuclear shift and with persistence in eosinophils is of good significance, and may not indicate a pathological state at all; e. g., such a condition occurs in pregnancy, where, however, the percentage of eosinophils may drop without any appreciable fall in the absolute numbers of this type of cell; this applies mainly to the later months of gestation.

2. Slight or well marked leucocytosis with definite nuclear shift of moderate degree, decrease of eosinophils, and slight decrease in the number of lymphocytes indicate a condition in which further examinations would be necessary before a prognosis could be given, although there could be no doubt of the presence of infection.

3. High leucocytosis with great shift to the left tending to progress in the same direction, with very great decrease or even disappearance of eosinophils and reduction of lymphocytes, is indicative of a grave condition, which may, however, still be recoverable. It is particularly when the young forms are in excess of those of band type that the prognosis is grave.

4. Recovery does not occur in those cases in which there is progressive fall of the total number of leucocytes with an extreme degree of shift to the left, total absence of eosinophils, and well marked lymphopenia.

5. Progressive eosinopenia with rising leucocytosis is never of good significance, unless

6. There is reappearance of the eosinophils and fall of the neutrophils, with reversion of the nuclear picture to normal, together with rise of the lymphocytes. It is clear that (5) represents the blood picture at the onset of an infection, and (6) the changes as it is overcome.

7. The development of lymphopenia during long continued leucocytoses is of bad significance.

8. Sudden fall of lymphocytes in association with increasing neutrophilia and progressive nuclear shift to the left is of very grave significance, as is also a sudden fall of lymphocytes, occurring during the course of a progressive decrease of the total number of leucocytes.

9. Lymphocytosis following neutrophilia, and accompanied by progressive passage of the nuclear shift towards normal and by eosinophilia, indicates recovery.

The Snare in Abdominal Surgery.—C. E. Farr (*American Journal of Surgery,* 1:1 new series) pleads for a revival and extended use of this instrument, in the following terms:

A rapid survey of the abdominal field will readily disclose a number of situations in which the snare can be profitably used. Its small size, its ease of handling, its firm grip of the tissues and the readiness with which that grip can be released, all commend it highly.

In pylorectomy the handling of the duodenal stump is of the utmost importance. Except in the Billroth 1 method, this stump must be crushed and carefully inverted to prevent leakage. Here the snare is ideal in safety, convenience and speed. The lumen of the gut can be closed by ligature, suture, or a combination of the two. The wire of the snare is loosened only after the inversion is completed and the sutures nearly drawn tight.

For temporary control of hemorrhage in large pedicles,

masses of omentum, etc., the snare can be used with safety and speed. After the removal of tumor, cyst, or omental mass, one can clamp and ligate the exposed vessels separately at his leisure, or pass a mass ligature or suture. No time is lost and the exposure is far better than that obtained by the use of heavy crushing clamps.

In resections of the bowel, especially the large bowel, the snare is readily adaptable to the socalled aseptic methods of resection and suture. The end to end, end to side, or lateral anastomosis can be quickly and safely performed with a minimal chance for leakage.

The great advantage of the snare is easily demonstrated, in that the wire can be loosened and withdrawn after the inversion stitch is completely placed and nearly drawn tight. In end to end anastomosis the primary and secondary sutures can nearly all be placed and tied before the snares are released and withdrawn. The opportunity for contamination is almost nil.

Occasionally nephrectomy is a most difficult operation because of inability to expose the pedicle and safely apply clamps. In such cases the wire of a snare can often be laid in place and easily set home. The same is true in high amputations of the rectum. The added inch of bowel that can be safely removed in this way may prove the deciding factor for ultimate cure. A further advantage is that, if needed, the snare may be left in situ until its work is done.

Easy Method of Performing Tracheotomy.—Kenelm H. Digby (*Lancet*, January 16, 1926) suggests the following technic for performing tracheotomy:

The child is held on its back on a flat surface. An assistant on the child's left places his right hand on the child's forehead and his left hand on the child's occiput and extends the head to the maximum point. The chin is raised so far that the front of the neck is a flat surface from the sternum to the point of the chin. A median skin incision is made 1.5 inches long vertically downwards starting from the upper border of the cricoid cartilage. The deep fascia uniting the sternohyoid muscles is divided vertically. The cricoid cartilage is exposed and the fascia, attached to its lower border, is incised transversely to expose the commencement of the trachea. A single closed pair of pressure forceps is passed downwards and backwards close to the trachea and behind the isthmus of the thyroid gland. A very slight opening and shutting of the forceps may assist their passage. The tissue thus raised is clamped close to the middle line first by one pair of forceps and then by a second pair placed parallel. The fascia and thyroid isthmus between the forceps are then divided and the two pressure forceps are each rotated in a lateral direction through 90 degrees and the handles are slightly depressed so as to raise the points. The rotation of the forceps usually peels the tissues from the trachea sufficiently to expose its anterior aspect, but a touch of the knife at either side will fully lay bare the front of the trachea. As the thyroid gland is intimately connected with the trachea and the cricoid cartilage, this maneuvre raises the trachea to the level of the skin, exposing the first four rings with utmost clearness. The vertical incision through the second, third and fourth rings should not be made by the "guarded stab" but should be gently incised with the knife held penholder fashion, the little finger of the right hand resting on the upper border of the manubrium. The stab is to be avoided because the trachea is flattened anteroposteriorly by thus being brought to the surface, and the posterior wall would be in danger.

Breast Operation with Endotherm Knife.—H. A. Kelly and G. E. Ward (*Annals of Surgery*, 83:1) assert that breast operations can be performed by this method without the use of a single ligature. They list the advantages as follows:

1. Lymphatics, capillaries and small bloodvessels are sealed, limiting the number of clamps applied. There is reasonable hope that this closure of the lymphatics will lessen the liability to local recurrences.

2. Few or no ligatures are used. The elimination of ligatures helps keep hands out of the wound. The operation can thus be done with hands, at a distance, lessening the chance of infection.

3. Primary union is the rule; the actual depth of tissue destruction on each side of the acusector is one tenth millimetre. It is easily possible that primary union is promoted because of sterilization of the skin edges.

4. The reduction of ligature material is no mean economical saving.

Erythrocyte Reaction in Surgery.—E. H. Rubin (*Surgery, Gynecology and Obstetrics* 42:5) has found that in surgery the erythrocyte sedimentation reaction is a more reliable indication of the condition of the patient than the temperature chart. Its diagnostic and prognostic value were secondary to its value in indicating the acuteness of a process. Extrasurgical complications such as syphilis or tuberculosis tended to maintain high readings in spite of the improvement or even cure of the surgical affection. In the absence of such complications, repeated tests may guide in the discharge of patients, although for many reasons it would be impractical to keep patients in the hospital until the reaction had reached normal limits. Because the test indicates the severity of tissue destruction, it should be of value in determining the advisability and time for operation.

Endoaneurysmoraphy.—R. Matas (*Surgery, Gynecology and Obstetrics* 41:6) advocates this type of operation as the simplest, surest, and safest method in his experience. He says that the surgeon should be eclectic in his attitude. He should choose the simplest means by which he may suppress the disease. It is in adopting this principle that the author says that he always begins an attack on the innominate, the subclavian, the carotid, the iliac, and the iliofemoral aneurysms, by first occluding the main artery with an aluminum band or, preferably in innominate and left subclavian aneurysms of the first or intrathoracic portion, by tape ligature, without interfering directly with the sac.

It is admittedly a serious enough matter to apply a ligature upon the innominate, or a subclavian, especially at the origin of these vessels, but the procedure, difficult as it is, is far less dangerous or risky an undertaking than to attempt to obliterate or extirpate the aneurysmal sac at the same sitting.

It should be borne in mind that in probably eighty to eighty-five per cent. of these cases, the simple occlusion of the main artery is sufficient to obtain a cure of the aneurysm. If a relapse follows, it is then time enough to obliterate or extirpate the sac.

In the young with aneurysms of direct traumatic origin who are free from syphilis or other constitutional taint, and especially in dealing with arteriovenous aneurysms, the author does not hesitate, in a general way, to attack the aneurysm by a direct free incision into the sac, followed by the suture of all the communicating openings within the sac. But, even then he never attempts such a procedure without the most thorough control of the main or injured artery, above and below the sac, by preliminary provisional hemotasis, with clamps, bands, or temporary elastic ligatures.

ANESTHESIA

Nonvolatile Aliphatic Compounds in General Anesthesia.—Robert K. Lambert (*Lancet*, January 16, 1926) suggests that by the preliminary use of nonvolatile aliphatic compounds in general, and more particularly by a mixture of isopral and hedonal, the following benefits may result: 1. The patient may be made drowsy and content, or completely somnolent before leaving the ward. 2. The completion of the anesthesia by gaseous anesthetics may be facilitated, and the duration of their use be reduced. 3. After operation, the patient may fall into prolonged and healthy sleep. Because up to date only small and tentative doses have been administered to man these benefits have not yet been obtained, but the results of animal experimentation encourage the hope that they will be found to accrue.

The Blood Nitrogen in Spinal Anesthesia.—Abadie, Baldous and Dornier (*Presse médicale*, March 27, 1926) find that operations conducted under spinal anesthesia are always followed by an increase of blood nitrogen lasting, on an average, one week. Important factors in this azotemia are the operation itself and the previous condition of the patient. The increase of blood nitrogen is much greater after severe operations, and is also more pronounced in patients with renal or hepatic impairment and in old age. The spinal anesthesia itself, however, also plays a part in the azotemia. The latter is notably greater with stovaine than with novocaine. While it seems unjustifiable to state that spinal anesthesia is without effect on the kidneys, the procedure nevertheless retains many advantages over the general anesthetics, and should not meet with disfavor on this account. Nor should stovaine be abandoned, for it has advantages in its rapidity and constancy of action. Furthermore, in some operations on the viscera it is useful in lowering the blood pressure, thus facilitating the operative

procedure and rendering it almost bloodless. In future, however, novocaine should be substituted for stovaine in patients whose kidneys or liver seem especially weak. In such patients, the inconvenience of having to wait ten or fifteen minutes more for proper anesthesia is more than counterbalanced by the greater assurance of safety in respect of the functions of the liver and kidneys.

Adrenalin in Ear, Nose and Throat Surgery.—G. Laurens (*Bulletin de l'Académic de médecine,* November 24, 1925) discusses the toxic effects that may be produced by adrenalin unless certain precautions are taken. During the operation these effects may consist of pallor, often with faintness and small pulse, accelerated heart action, and frequently a sharp nuchal head pain, with or without dizziness. Twice the author even witnessed epileptoid convulsions. These toxic manifestations of bulbar ischemia seem attributable to introduction of adrenalin into the intracranial circulation and possibly to unintentional intravenous injection. They generally appear one or two minutes after the injection, sometimes last fifteen minutes, and subside either spontaneously or after a few injections of camphor in oil or of ether. They result almost always from submucous intranasal injections of adrenalin. Postoperatively the drug may, if used in excessive amounts, lead to secondary hemorrhage and the formation of hematomas, which may suppurate and require reopening of the wound and ligation. Minor effects are transitory hydrorrhea, dental neuralgia and the formation of pseudomembranous scabs. To obviate such untoward results it is necessary to use only pure, fresh adrenalin solutions, to be added to the procaine or cocaine just before use. Old, deteriorated solutions are less vasoconstrictive but more toxic. Local applications of adrenalin, even in unusual quantities, only very exceptionally cause toxic symptoms, but in subcutaneous and especially submucous injections it is wise not to exceed twenty-five drops of 1:1000 adrenalin in 100 units of procaine solution. In sensitive or pusillanimous patients the injection should be made very slowly and cautiously. In nasal surgery, in submucous injections, especially in the ethmoid region, abrupt introduction of adrenalin and, in particular, injection of large amounts into the septum must be absolutely avoided. The most reliable measure for obviating difficulties is to apply 1:1000 adrenalin solution over the surface of the mucosa a few minutes before the actual injection. A barrier is thus established against absorption of the drug. Further, the injection should be made very slowly and evenly. With these precautions the author has practically eliminated all untoward effects from adrenalin in his surgical practice.

Intravenous Anesthesia by Allylisopropylmalonylurea.—P. Fredet (*Paris médical,* December 5, 1925) describes this drug as a rapidly acting anesthetic with effects persisting for a few hours. A ten per cent. solution of the drug is used; the drug is brought into solution by addition of a slight excess of diethylamine, and the solution stabilized by further addition of a little alcohol and glycerin. The drug is carried about in the blood chiefly by the blood cells and has a strong affinity for the nerve centres; but little of it is taken up by the body fat, liver and kidneys. It is eliminated unchanged in the urine. The elimination begins very promptly, but is slow, some of the drug being still found in the urine after ten days. The respiration and circulation are but little affected by this anesthetic. There is a slight rise and secondary fall in the respiration and pulse rates. The blood-pressure descends slightly after the injection, but rises gradually toward normal during the operation. The hepatic and renal functions are practically unaffected, as shown by various tests. The drug is not relied on as the sole anesthetic, but its action is supplemented by other agents which perfect the anesthesia. A hypodermic of one to two centigrams of morphine hydrochloride in one per cent. solution is first given, preferably with two thirds to three fourths milligram of scopolamine hydrobromide. Twenty to forty-five minutes later, the solution of allylisopropylmalonylurea is injected slowly in a vein at the elbow. In adults in good condition the dose is one-tenth mil. of the solution per kilogram of body weight, up to a maximum of seven mils. In aged or cachectic persons, four mills should not be exceeded. About five minutes after the injection, a few whiffs of chloroform or ether are given. The operation is begun about ten minutes after the injection. When the incision is finished, the inhalation anesthetic can generally be dispensed with, though a few further whiffs may be required later if the patient should move or at the end of the operation, during the suturing. By this method, which the author has applied in ninety-one human cases, an excellent anesthesia is obtained which lasts two or three hours and permits of ready execution of such operations as hysterectomy, operations on the liver and stomach, operations on the extremities, such as resection of the knee, etc. After the operation the patient continues to sleep quietly or is somnolent for four or five hours. Vomiting is exceptional; therefore the patients can be fed up to the time of operation and can take fluid and food immediately after, thus obviating starvation, acidosis and thirst. For operations such as radical cure for hernia, appendicitis, etc., requiring only a shorter anesthesia, the author continues to use chloroform or ether.

Albromine, a New Local Anesthetic.—Rolf Roman (*Hygiea,* April 15, 1926) after giving a brief general retrospect of the development of surgical anesthesia and particularly local anesthesia by means of cocaine and later novocaine, proceeds to give his experience with an anesthetic of more recent date named *albromine* by its originator, R. Eckermann, Ph.D., D.D.S. It is stated by him to have been empirically obtained and to consist of a colloidally transformed cocaine hydrochloride, treated under special conditions with an excess of phenylurethane, the latter having been previously colloidally prepared. Leaving it to the originator to deal with the chemical composition of this preparation and related questions in his own publication, he considers its usefulness from the point of view of surgery. Reference is made, however, to some experiments on animals in which a solution of albromine (0.025 per cent.) is shown to be more effective and yet more easily vaporized than a similar solution of cocaine or novocaine; its effect is found to be 20 times stronger than cocaine and more than 20 times stronger than novocaine. Empirically the maximum dose of albromine for a human adult, subcutaneously injected, is 250 c.c. of a 0.5 per cent. solution. In comparison with the pharmacopeial maximal doses of cocaine and novocaine, albromine is found in practice to be 25 times less poisonous than cocaine and 2.5 times less than novocaine. The practicability of using albromine in general surgery is exemplified by a survey of the different operations that it has been used for and by a limited number of clinical accounts of operated cases, and definite acknowledgment is made of its usefulness, in so far as it satisfies the need of a reliable anesthetic, harmless, and of sufficiently lasting effect—this while emphasizing the fact that several investigations remain to be concluded before final scientific judgment can be given regarding the new agent.

Spinal Anesthesia in Abdominal Surgery.—Carl H. Bastron (*Northwest Medicine,* May, 1926) asserts that with nontoxic drugs and a faultless technic spinal anesthesia is practically devoid of danger, and is a practical procedure in all operations below the diaphragm. Failures are almost always due to faulty technic. It is not contraindicated in pulmonary tuberculosis, heart disease, and low blood pressure. Preoperative stimulation is of little value in prevention of blood pressure drop. The symptoms of collapse after spinal anesthesia are not due to the lowered blood pressure, but to the suddenness of this lowering.

GYNECOLOGY AND OBSTETRICS

The Bell Bettner Operation.—W. B. Bell (*Surgery, Gynecology and Obstetrics,* 42:1) presents his operative technic, for ovarian conservation or grafting, revised as follows:

1. As in dealing with any case of salpingitis, it is important for the surgeon, after separating adhesions to omentum and bowel, if these be present, to free completely the adherent tubes and ovaries and also the uterus if it be bound down in a position of retroversion.

2. The infundibulo pelvic and round ligaments are ligated together on both sides, if the ovaries are to be removed, and an additional ligature is tied round each infundibulopelvic ligament as a measure of safety.

3. If one ovary can be retained in position, the mesosalpinx of the same side is divided as close to the affected tube as possible. Vessels are caught in forceps and ligated subsequently. A ligature placed around the ovarian and round ligaments includes the terminal anastomotic branches of the uterine artery on this side.

4. After the ligation of vessels mentioned, according to the intention of the surgeon, to leave an ovary in situ or not, a transverse flap of peritoneum of the uterovesical pouch

is raised, and the uterine arteries on either side are ligated at a level about one half or three quarters of an inch above the internal os uteri.

The entire blood supply of the parts concerned is thus arrested, and the operation should be almost bloodless.

5. The ovaries and tubes are cut free on either side—unless the tube on one side has already been detached leaving an ovary in position—up to the lateral aspects of the uterus above the ligatures placed on the uterine arteries.

6. A transverse wedgeshaped portion of the fundus is now excised by means of anterior and posterior incisions.

7. The V shaped raw area left in the uterus, with the lower part of the uterine cavity showing in the angle, is closed by means of the mattress and over suture, which the author employs so frequently in operations involving suture of the uterus and of the vaginal walls, and which is best effected with a Reverdin needle. The mattress stitches, when tied, bring into apposition the deeper parts of the uterine wound, and the "over stitches," made with the long ends of the threads left after the mattress stitches have been tied, close effectively the edges.

8. The pedicles on either side, in which are contained the round and infundibulopelvic ligaments, or on one side the round ovarian ligaments, are fixed by means of a suture fairly high on the back of the utriculus. By this means the small uterus is kept forward, an important consideration if there be raw surfaces in the pouch of Douglas, where adhesions have been separated.

9. The flap of peritoneum which was raised from the uterovesical pouch is now brought over the utriculus, and sutured to the posterior wall. In this way the line of suture at the summit of the small uterus is completely covered. In a like fashion with lateral sutures the attachment of the pedicles to the posterior surface of the uterus are covered smoothly with peritoneum.

This last detail of technic is most important, for intestinal adhesions to the line of suture in the uterus would be most difficult to prevent if a covering of peritoneum were not used.

Anterior Abdominal Hysterotomy.—P. Oginz (*Surgery, Gynecology and Obstetrics,* 42:4) asserts that the operation of hysterotomy for the interruption of pregnancy and sterilization is of great value in certain cases of pulmonary tuberculosis, cardiac diseases, chronic nephritis and hypertension, and some unusual cases; and could be used to the patient's advantage much more often than has been the practice in this country. The technic which the author advocates follows:

A midabdominal incision is made from an inch or two below the umbilicus to the symphysis. The uterus is seized by a tenaculum, brought out of the abdomen, and then well walled off by lap sponges. A four or five centimetre incision is made in the midline beginning at the fundus and extending toward the cervix through all the uterine coats. The membranes usually bulge through the incision and are ruptured. The embryo and placenta are detached and removed with a gauze wrapped finger or a sponge stick forceps introduced into the cavity of the uterus. Here a little difficulty is encountered because the spongy layer of the decidua is not fully developed and does not separate easily. There is little bleeding from the placental sinuses. The delivery of the membranes and the placenta is followed by an injection of one cubic centimetre of pituitrin directly into the uterine musculature. This contracts the uterus fairly well. A continuous suture of No. 2 plain catgut brings the musculature of the uterus together, but does not take in the endometrium. A second seromuscular layer of continuous No. 2 plain gut followed by a peritonealization of the raw surface, closes the uterus firmly, preventing any possible leakage. The tube is now grasped by an artery clamp at its isthmic portion and picked up, so that a knuckle is formed. A fine needle carrying silk is passed under the tube at the apex of the knuckle and tied first over one limb and then over the other. The apex of the knuckle is cut off with the scissors and both raw surfaces are cauterized by thermocautery or carbolic and alcohol. The same is repeated on the other tube. A rapid inspection is then made and the abdomen is closed. The operation is followed by as little postoperative inconvenience as that following an interval appendectomy. In the author's series of cases little pain was experienced and the temperature never rose to over 100.5° F. The patients were returned to the care of the medical men on the tenth or twelfth day after the operation. During convalescence, very moderate vaginal bleeding due to the throwing off of small placental rests is a common finding. Not a single one of my cases showed any morbidity.

The operation can be done at any time during the pregnancy. In the early months a two inch abdominal incision, just large enough to admit two fingers, may be adequate for the entire operation.

Cæsarean Section at Cook County Hospital.—In a series of one hundred and sixty-six cases H. F. Lewis (*Surgery, Gynecology and Obstetrics,* 42:6) reports a death rate of seven per cent. Of the various types of operation employed, the classical operation of Saenger was the one most frequently used. Eighty-seven such operations are included in the one hundred and fifty-eight cases belonging to this series. Six patients were operated upon by the Porro method. One vaginal Cæsarean section was done. The low cervical operation of Kroenig was done by two of us. These operations numbered forty-eight. One operator employed the low incision through the abdominal wall with the longitudinal incision through the lower segment and cervix; the other made a transverse opening through the cervical muscles, usually with the fingers. The former method Lewis termed the low cervical and the latter the transverse cervical. There have been thirty-five low cervical and thirteen transverse Cæsarean sections.

Another type of operation has been done by two operators at the hospital for a few years. This I will call the longitudinal fundal Cæsarean, of which there were sixteen cases. The incision, long enough to allow dislocation of the uterus, is made in the abdominal wall in the median line about half above and half below the navel. After the uterus has been everted the abdominal wound is temporarily held together by means of one or two vulsella and the base of the uterus is lightly packed with gauze. Thus the spill is well controlled and we rarely have any fluids leaking into the belly. The uterine incision is made longitudinally in the median line of the fundus of the uterus, large enough to permit delivery of the baby and extending equally fore and aft. By tilting the uterus the spill can be directed away from the wound. One advantage is that the uterine wound is as far as possible away from the usual source of infection, which is almost always via the genital canal. It is the ideal method for the case of placenta previa in which the Cæsarean operation may sometimes be indicated.

Rupture of the Uterus.—J. G. Sherrill (*Surgery, Gynecology and Obstetrics,* 42:5) says that among the many causes of this complication the use of pituitrin is of considerable importance. Its use early in labor may be followed by rupture. Sudden collapse during the progress or at the completion of labor is of great diagnostic value in cases of rupture and should at once suggest its occurrence. Uncontrollable hemorrhage after the delivery of the child and placenta should cause one to suspect rupture of the uterus, either partial or complete. Inspection of the source of the hemorrhage should clear up the diagnosis.

The important causes of death are hemorrhage, shock, and sepsis. Many of these deaths are undoubtedly the result of illadvised or protracted efforts at delivery before the condition is recognized. It is evident that prompt recognition and surgical intervention will show marked decrease in the mortality.

The treatment of these cases at operation consists in suture of the torn uterus or in hysterectomy. When there is any doubt regarding the presence of infection, removal of the uterus is preferable. In the absence of infection, suture of the rent as in Cæsarean section may be employed. It does not appear in the light of advanced surgical technic that the employment of tamponade would be wise except in those cases in which competent surgical help cannot be obtained.

Sedimentation Test.—H. L. Frosch (*American Journal of Surgery,* 40:5) finds that a sedimentation time of more than two hours is of no diagnostic value. An increasing sedimentation time means that the patient is improving. A diminishing sedimentation time means that the patient is getting worse. The prognosis is poor in any case having a persistent sedimentation time of less than one half hour. Any surgical case having a sedimentation time of less than one half hour requires an immediate operation. This test is of no aid in the diagnosis of pregnancy. In gynecological pelvic conditions it is an aid both in differential diagnosis and also as in determining the time of operation.

STATUTE APPORTIONING COST OF COUNTY TUBERCULOSIS HOSPITAL HELD CONSTITUTIONAL

Massachusetts St. 1924, c. 443, provides that all the cities and towns of Essex County, including those previously exempted by St. 1916, c. 286, should constitute the Essex County tuberculosis district and be subject to all the provisions of the general law as to care of persons suffering from tuberculosis. The cost of maintenance, operation and repair of the county tuberculosis hospital is to be assessed upon all the cities and towns of the county in accordance with their valuations. In Essex County v. City of Newburyport, 150 N. E. 234, the constitutionality of the statute was challenged so far it required the city to pay a part of the cost of the county hospital. The Massachusetts Supreme Judicial Court holds that the statute contained nothing arbitrary, despotic, or constituting a flagrant misuse of legislative power such as would render it unconstitutional; and it authorized no taking of property without due process of law contrary to the Fourteenth Amendment.

VERIFICATION OF SKIAGRAPHS INTRODUCED IN EVIDENCE

In a proceeding under the Illinois Workmen's Compensation Act, the claim being that the claimant strained a kidney and the muscles of his back while lifting a pit car on a mine track, skiagraphs were used as the basis of the testimony of some of the witnesses who testified as to the extent of the claimant's disability. The Illinois Supreme Court held, Madison Coal Corp. v. Industrial Commission, 150 N. E. 724, that a proper foundation was not laid for the use of the skiagraphs, and that the testimony based thereon was inadmissible, under the rules laid down for the use of such testimony in Stevens v. Illinois Central R. Co., 306 Ill., 370, as follows: "Although a skiagraph produced by x rays cannot be verified as a true representation of the subject in the same way as a picture made by a camera, the rule in regard to the use of ordinary photographs on the trial of a cause applies to skiagraphs of the internal structure and condition of the human body taken by the aid of x rays, and such a skiagraph, when verified by proof that it is a true representation, is admissible in evidence. Like other photographs, they cannot be received as evidence until proper proof of their correctness and accuracy is produced. It must be established by competent evidence that the picture correctly portrays the condition it purports to represent before it has any place in the case. Some witness must be able to testify that the picture offered in evidence shows accurately what the witness saw when he looked into the body with the fluoroscope, or he must be able to say that he is skilled in the use of the X ray machine and in taking and developing x ray pictures, and that he took the picture offered in evidence with the body in a certain position (describing it), with a machine which he knew to be in good working condition and accurate, and that from his experience he was able to say that the picture produced by the machine was an accurate picture of the internal condition of the body. These methods of establishing the accuracy of the picture are not exclusive, but whatever method is used its accuracy must be established before it is admitted."

It was also held error to permit the medical witnesses to detail complaints of the patient and his manifestations of pain which were within his control, and then express an opinion as to the patient's condition based thereon.

MISREPRESENTATIONS AS TO HEALTH IN APPLICATION FOR INSURANCE POLICY

Where the evidence in an action on an insurance policy showed that the insured, at the time of his application for the policy was suffering from cancer and within twelve months prior to the application had undergone a surgical operation for its removal, and that the disease was a contributing cause of his death a few months after the issuance of the policy, the Alabama Supreme Court held, Miller v. Metropolitan Life Ins. Co., 106 So. 335, that a representation in the application that his health was good was necessarily false and material to the risk, and no recovery could be had on the policy.

Where an application for fraternal insurance warranted answers, whether written by the applicant or not, a false warranty that he had not had certain diseases (tuberculosis, appendicitis, paralysis and spitting of blood) and had not within five years been attended by any other physician than was stated in the application, was not waived because the insurer's physician made out the application; it not appearing that the physician was advised as to the true facts or that the insured did not fully understand the answers as written. Sovereign Camp, W. O. W. v. Prince (Miss.) 106 So. 521.

REFUSAL TO SUBMIT TO OPERATION HELD WARRANTED

Where the expert witnesses in a Workmen's Compensation case were equally divided as to the nature and cause of the claimant's cataract and whether an operation would be successful, the Alabama Supreme Court held, Gulf States Steel Co. v. Cross, 106 So. 870, that the court properly declined to suspend compensation for refusal to submit to an operation.

TUBERCULOSIS RESULTING FROM INJURY HELD COMPENSABLE

The Texas Court of Civil Appeals holds, Aetna Life Ins. Co. v. Graham, 279 S. W. 923, that if the fumes incident to the mixture of chemicals in making shoe polish, inhaled by a worker, produced and kept the membranes of her nose, throat and lungs in an irritated condition, this was an injury to the physical structure of her body; and if, on account of or by reason of said irritated condition, tubercular germs seized upon said injured parts and developed into tuberculosis, that disease "naturally resulted from said injury" and was compensable under the Texas Workmen's Compensation Law. It was not necessary, under the Texas statute, that the injury should have resulted from an accident, or whether the injury and its resultant disease developed suddenly, or gradually and imperceptibly.

BURDEN OF PROOF OF LICENSE ON PHYSICIAN

The Alabama Supreme Court holds, Cummings v. State, 106 So. 852, that the treatment of human diseases is Alabama is a profession, and this profession cannot be lawfully practiced by a person in the state without a proper license or certificate of qualification. In quo warrants proceedings by the state to exclude the defendant from practising the profession of treating human diseases without a license, it was undisputed that the defendant was in the profession of a chiropractor and held that he was prohibited by statute from practicing unless he had authority by certificate or license to do so. It was held that proof of these acts by the state made a prima facie case against the defendant, and cast on him the burden of showing authority by proper certificate or license to practice that profession, as the proof of these facts was peculiarly within his knowledge.

Mental and Physical Rest in Pulmonary Tuberculosis*

S. ADOLPHUS KNOPF, M.D.
New York

Of all the remedies employed to effect a cure in pulmonary tuberculosis, whether they were symptomatic or thought to be specific, none has gained for itself a lasting reputation. Tuberculin, the nearest approach to a specific, even when employed with the utmost care, has proved useless and even dangerous unless the rest is also given. General rest for the body, local rest for the invaded organ, freedom from anxiety of the mind, a cheerful and restful spirit, combined with rational hygienic and dietetic measures are today the universally accepted therapeutic measures for pulmonary tuberculosis. By their employment, thousands have been saved; by their neglect, an equally large or larger number of valuable lives have been lost, many in the very prime of life. The object of this paper is then to study what we can do to add to this sovereign remedy of rest, and make it most efficient.

We will first discuss the case of the ambulant patient who comes to our office for the first time. In the very act of greeting him we should make him feel that we are so interested in his case that we prefer to have a special time when we can examine him more thoroughly than during office hours when there are a number of patients to be seen. It will rather please the patient to have this manifestation of interest in his case and he will certainly feel better mentally than if obliged to wait in a crowded reception room with coughing patients who may not always bear in mind the danger of droplet infection.

The patient is received at the time set for the examination, but is allowed to rest a few moments in the well ventilated and well lighted reception room where he may have some pleasant pictures to look at on the wall and some fresh literature to glance over, instead of being obliged to handle soiled and tattered magazines.

The potential pulmonary invalid is called in from the reception room by the physician himself or by a pleasant voiced nurse whose manner should inspire confidence. While the anamnesis is being taken and inquiry being made to elicit as much as possible of the personal and family history, the observing physician will try to learn all he can of the mental attitude of the patient. It goes without saying that the physician must be free from all preconceived opinions and not belong to that class of medical men, alas not entirely extinct, who look upon the pulmonary individual, as psychically abnormal. I regret that even in a recent otherwise excellent textbook (1) we may read the following statement: "A psychic trait of the consumptive which has been noted by most writers is selfishness. He becomes egotistical and egocentric, he is interested in the welfare of but one person—himself—to the exclusion of all who have depended on him before. He will eat costly food while his children starve; he will make unreasonable demands on his relatives and friends and show no gratitude. In sanatoria this has been the most important problem with which the officers have to cope, and the failure of many superintendents is due to their lack of appreciation of this trait of the consumptive."

Dr. George H. Crofton (2) speaks of the mental phase of pulmonary tuberculosis and concludes by saying: "In general, the mental reactions of the phthisical patient may be said to indicate a reversion to childishness. . . . The patient has a tendency to react in a primitive, instinctive manner, acting upon impulse, driven by his unbridled emotions, at the mercy of his own undisciplined will." An article by B. J. Weigel, of the Albuquerque Sanatorium, New Mexico, states that among two hundred tuberculous patients he had studied carefully, ninety-four were suffering from a definite psychoneurosis or psychosis.

I hope that none of my readers will share this opinion concerning the average tuberculous patient, especially when we think of the great men in my own profession who, though tuberculous, have been more altruistic, more selfsacrificing, and of finer intellect, and who have made greater contributions to medical science than many of us in the prime of health and vigor. I need only mention such names as the immortal Trudeau, the valiant surgeon soldier, Colonel Bushnell, the genial Herbert M. King, of the Loomis Sanatorium, to represent this country. Then we think of Laennec and Grancher of France, Brehmer and Dettweiler of Germany, Buddington of England, Saugman and Finsen of Denmark, and many authorities on tuberculosis in other countries, not to mention the still active eminent American phthisiotherapeutists, well known to all of us (4).

Some years ago, when official and private phthisio-

Copyright, 1926, by A. R. Elliott Publishing Company.

phobia was rampant, I wrote an article under the title of "A Plea for Justice to the Consumptive" (5), for which I collected the opinions of many men on the subject of the mentality and alleged egotism of the average tuberculous individual. In a charming letter I received from Dr. Trudeau, he wrote: "I have seen certainly more patience, courage, selfdenial, and unselfish devotion to others in consumptives than I have noticed in the majority of healthy human beings. Indeed the sanatorium work never could have been carried on were it not for the selfsacrificing devotion to the suffering of others shown by my associates, the nurses, and even the employees at the sanatorium, most of them having come here originally because suffering from tuberculous disease. History is full of instances which prove that tuberculosis does not interfere with the development of the highest degree of the intellectual, the moral, or the ethical sides of man's nature."

That keenest of medical observers, the late Sir William Osler, said: "My impression is that the unfortunate victims of tuberculosis are above the average in their mental and moral character."

With this thought in mind, let the physician approach his patient with the questions that will give him all the facts he desires to have in order to form a background for the patient's case. Even before asking any questions, the physician may have observed an increasing pulse rate because of mental agitation. A few calming and encouraging words, assuring the patient that tuberculosis is not at all a hopeless disease, will help to quiet him. At times, a patient may come for examination who has already been diagnosed as a suspicious case by another physician and has been sent, or come on his own initiative, for confirmation of the diagnosis. In either case he may present a veritable fear complex. He fears to lose the doubt about his being tuberculous; he is thoroughly apprehensive that as the result of a definite diagnosis there will be ostracism, isolation, separation from his family, ultimate suffering and early demise. Sometimes to all this is added the fear of losing his position if he is an employee and in moderate circumstances. Step by step such a patient must be convinced of the groundlessness of his fears. The curability of the disease must be dwelt upon and the marvelous reduction of the disease by our modern methods of cure pointed out to him. He may be told of the endless number of men and women who have accomplished great things in life while still afflicted with and after having been cured of tuberculosis. Such were Honore de Balzac, the great French novelist; Elizabeth Browning, the noted English poetess; Lord George Byron, the celebrated English poet; the famous Polish composer and pianist Chopin; our own Ralph Waldo Emerson; the great German poet Goethe; the celebrated German lyric poet and critic Heinrich Heine; the great American historian and novelist Washington Irving; Samuel Johnson, the celebrated English lexicographer and essayist; the German philosopher Immanuel Kant; John B. P. Molière, the greatest French writer of comedies; the celebrated Italian painter Raphael; the German poet Schiller; Spinoza, the philosopher; the well known author Robert Louis Stevenson; the celebrated American writer Henry D. Thoreau, the famous French philosopher and writer Voltaire, etc. When the physician asks about the probable hereditary tendency, let him embrace the opportunity to assure the patient that, even if his father or mother may have died of the disease, this by no means signifies that he too is doomed, for we do not consider tuberculosis as hereditary but rather as a disease transmitted from person to person. At this state of the anamnesis a few words cautioning against infection from tuberculous sputum carelessly deposited, or through coughing without holding the hand before his mouth, may be *apropos*.

When it comes to the question whether the patient has had a hemorrhage or bloody expectoration, an excellent chance arises to quiet his fears. If he has had one and that was what brought him to be examined, he should thank his Creator for the incident, for otherwise the disease might have gone on to a far more advanced stage when the chances for a recovery might have been less good. If the patient has never had any hemoptysis, he should be prepared for the possibility of the occurrence, be told what to do, and be assured that a hemoptysis is no more serious than a cough, and that one or even several of them would by no means lessen his chances for recovery.

The patient should always be asked about the use of alcohol, drugs, or tobacco, and warned against their danger, be it a male or female patient; for nowadays we find the fairer sex at times indulging quite as excessively in cigarette smoking as men do, which, of course, is neither helpful as a preventive nor as a cure for pulmonary tuberculosis.

Occasionally, there will come to the physician who sees many cases of tuberculosis an individual with seeming psychosis or psychoneurosis which, on careful examination and analysis, will be found not to be due to tuberculous disease, but to the habit of taking some narcotic drug. The patient may have acquired this habit from the indiscriminate use of patent medicines containing habit forming drugs, from unscrupulous drug venders, or perhaps by the too frequent use of carelessly handed out prescriptions of cough mixture containing opiates. Such cases should be treated by gradual withdrawal of the drug and building up the general system, in addition to which we have the allimportant suggestion therapy. We must convince the patient of the true nature of his nervous affliction and that it is essential to have his cooperation in order to effect a cure.

The examination room of the phthisiotherapeutist, or for that matter of any physician, should of course be light and cheerful, well ventilated and also well warmed in cold weather to prevent chilling the patient in mind and body. The more thorough the examination, the more will the patient's mind be assured that he is in good hands and that what is humanly possible will be done for him. If the prognosis is favorable the patient should be told so, if doubtful or unfavorable, the patient should be assured that while the case seems somewhat serious it is certainly not hopeless.

The advice as to climatic change, if such is indicated, should be given only after having learned what the patient is financially able to do. It is obviously bad therapy to tell a poor patient or one in moderate circumstances to pack up and go to a distant climatic health resort. After having found out what the

patient can do for his own financial support and for how long, and having sized up the individual likes and dislikes for hot or cold climates, and found out whether or not a serious nostalgia would result from sending him away, the physician can easily make up his mind if the patient will be mentally and physically better off at home or away from home, in a sanatorium or hospital or in a hotel or boarding house at a health resort under medical supervision, and what climate might be best suited for him. The physician should bear in mind the maxim that where the patient is happiest and most contented and able to spend in comfort the greatest number of hours of the day and the greatest number of days of the year outdoors, and where the medical supervision and guidance is as nearly perfect as possible, is the ideal place to send him. This may be any place where the air is pure and the extremes of temperature not too pronounced.

Of course, one must never forget that there are patients who cannot be disciplined except in a sanatorium or hospital and who must be under constant medical supervision. There is one more point to be taken into consideration when selecting the climate for a patient, and that is when he expresses a desire for a particular climate, health resort or sanatorium because he had heard that there a certain patient whom he knew got well. Unless there is an absolute contraindication to his going there, it is best to yield. More mental peace and therefore perhaps an additional therapeutic factor will be gained thereby.

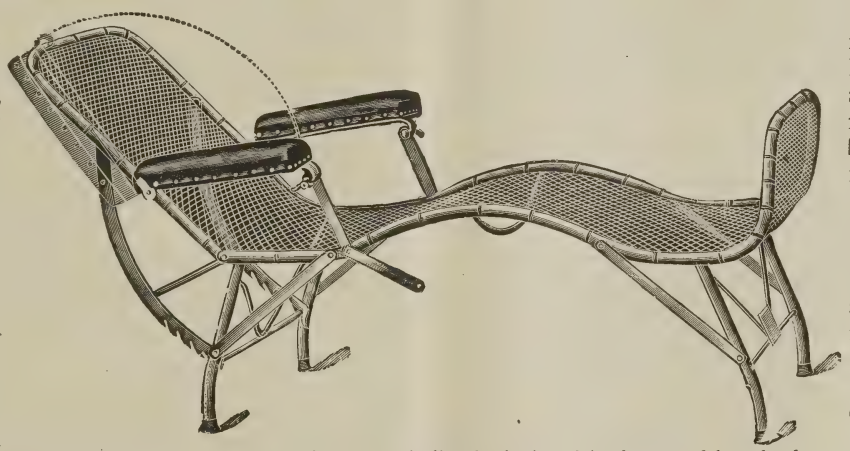

Fig. 1.—Reclining chair showing proper incline for back and head rest and knee bend to assure the least cardiac effort and facilitate complete relaxation.

In some sanatoria and health resorts the patient, whether febrile or not, is immediately put to bed on arrival for a period of from four to six weeks, followed by carefully graduated exercises; but with an afebrile patient it may be difficult to keep him always hopeful and cheerful and overcome all possible signs of nostalgia when confirmed to bed continuously and for so long a time.

Concerning the prescribing of exercise, which should of course be graded with a patient who has been at rest for so long a time, I recommend gentle massage of lower and upper extremities prior to beginning walking exercises. In determining how many minutes and how much should be the gradual increase in exercise, I find that the patient himself can be of great help by bearing in mind the following injunction: Never start to walk or do any kind of physical or mental work or exercise when tired, and always stop before getting tired. When hill climbing is the exercise, the patient should of course start with walking upward and return down hill when beginning to feel tired.

All patients should be enjoined to take as much physical and mental rest as possible, but in order to reap the benefit of rest the patient must know how to relax. Few of them know how and they must be taught how to attain complete muscular relaxation. The feverish patient should be at once put to bed and only after his temperature has subsided for a number of days in succession should he be permitted to start the rest or Liege cure on the reclining chair. The latter should be comfortable and have the right kneebend (Fig. 1). The ambulant and afebrile patient may be allowed to start his rest cure at once on the reclining chair.

Complete rest, at least one half hour before and one hour after the principal meals, should always be insisted upon, even for comparatively early cases with little or no activity. Absolute bed rest for active cases is of course the ideal treatment. The less the body moves in general and the less frequently the lung moves in particular, the better are the chances of recovery. Webb has well said (6): "Pulmonary tuberculosis is liable to relapse in many instances because rest, prolonged and as complete as possible, is not continuous. Until serial röntgen ray studies were made, it was believed that pulmonary tuberculosis deposits always became replaced by fibrous or calcified structures. We now know that in secondary lung infections of experimental animals, and also in phthisis, actual absorption of lesions does occur." In addition to this Webb also makes a statement concerning prolonged rest to which I am willing to add that one perhaps never errs in advising too long a rest cure for pulmonary tuberculosis but may regret to have advised too short a one. Here are Webb's own words concerning this: "Rest in pulmonary tuberculosis should be prolonged many months after the temperature and pulse have become normal, and sputum has disappeared. The tuberculous deposits in general start to clear away after six months of rest, but are not completely absorbed until from two to three years of rest. We must not be deceived by a drop in the patient's temperature. That is only the beginning of the fight. The patient should rest one year, or two, or sometimes even three years, but we must remember that a mind unoccupied is a mind distressed. The patient must be happy while resting."

To procure this happiness as well as physical and mental rest, it is essential that the environments should tend to make the enforced repose as pleasant as possible. When the patient's condition demands rest in bed within doors, his room should not only be well ventilated but pleasantly arranged. The bed must be comfortable, and if possible there should be two beds, one for day and one for night use. While

heavy dust catching furniture and draperies should never be in a sickroom, washable curtains, light furniture and pleasing pictures should help to make the room homelike and take away the hospital atmosphere. If the beds can be arranged on a veranda or so that the patient can look out of the window where he has a pleasant view, so much the better. It is largely for this reason that, whenever possible, the rest cure galleries in sanatoria are placed so that the patients may look upon a beautiful landscape. That the patient's rest in bed may be comfortable, he should of course have bed clothes according to the season—in winter the typical Adirondack bed—and never should he be put to bed or enter the bed in cold weather without it having been previously warmed. The bed should warm him and not he the bed. While sleeping in blankets has been recommended by many therapeutists, I do not favor it for sanitary reasons. In the Adirondack bed the sheets remain in place even with a restless patient, but if absolutely desired the blankets under or over the patient might be protected by a muslin bag.

No bed or even ambulant patient should be compelled to rise for the purpose of urinating and a urinal and chamber pot should be placed at his disposal, which he can use without uncovering himself more than the one arm to handle and to empty the urinal. Many a bronchitis has been contracted by ward patients being obliged to go to a distant toilet to urinate on cold nights when according to regulations all the windows were open for proper ventilation. Urinal and commode should always be resorted to, day and night in febrile cases, where absolute rest has been enjoined as an antipyretic measure. If there is a great deal of activity and temperature the patient should of course be put at the socalled typhoid rest. He should not be allowed to talk and should even be fed so as to avoid all possible physical exertion. Gentle sponging with tepid water may help in reducing the temperature. Coal tar products are apt to depress and are as a rule of little help, but the ingestion of large quantities of cold water will aid.

The bed patient who is only slightly feverish may receive a limited number of visitors, but only such as he really wishes to see. Those who are irritating and tiring to him should be rigidly excluded, and so should all those who are fond of relating that this, that, or another friend of theirs, who had the same trouble as he, were treated by this or that particular doctor, or in this or that particular climate.

Krause, in his charming little book (7), has well said: "It should hardly be necessary to point out the enormous amount of functional disturbances which the reactions of jarring personalities bring into being: nor are their effects on already established organic deficiency or disability any less marked. Every physician soon becomes familiar with them and is mindful to attempt to control them when treating his patients. There is a social and family environment of amiability and good fellowship and contentment and happiness; it may exist in surroundings which physically may be far from our accepted hygienic ideal: and its effect on the general well being of those happily situated in it is all good. This much is, I think, beyond dispute. But there is also a radically different environment: one of incompatibility, of oppression and brutality, and even bestiality. It is by no means the heritage or appanage of the hovel exclusively. It may dwell where air and space and light and food leave nothing to be desired; yet even here it will make for ill health."

The physical symptom which deprives the patient of the greatest amount of rest is of course the cough. While bed rest is an invaluable remedy, it is not always sufficient to control either the useless or the useful cough. The useless cough being merely due to an irritation in the larynx or a nervous habit, can be treated by psychotherapy, by telling the patient that he must try to suppress it by will power and that he is only allowed to cough when he feels that he must expectorate. A dietetic help to combat the tenacious sputum is the ingestion of plenty of table salt with the patient's meals. In urging to discipline his cough we must not fail to tell him never, under false modesty, to swallow his expectoration, as an infection of the intestinal tract may result. Little sips of water, a sudden inhalation, controlled diaphragmatic respiration—to which we will return later on—are also physical means to stop useless cough which is not only annoying to the patient himself, but also to those near him. My great teacher, Dettweiler, one of the pioneers of the sanatorium treatment, was in the habit of telling his patients that coughing in public merely on account of a tickling in the throat was as impolite as scratching the head in public because it itched. I have found that a more impressive warning is to tell the patient that useless coughing—that is to say, any dry cough—irritates the throat, and when the habit becomes chronic there is danger of laryngeal complication. If laryngeal complication does set in, or if there is fear of it, the ideal remedy is of course absolute rest of the vocal cords, and I always quote to my patients the case of Sir St. Clair Thomson, of London, who cured himself of a serious pulmonary and laryngeal tuberculosis by a year of absolute silence. That the useless cough can be completely controlled through psychotherapy has been amply demonstrated in sanatoria, where patients are taught to master the habit of useless coughing, and hardly ever cough at the table. Compared with any other place where the same number of people congregate, there is often less coughing in a well conducted sanatorium for tuberculous invalids.

Of course, there are some rebellious coughs which must be treated by medication. Cough mixtures with opiates may even become necessary; the same is true in some cases of excruciating pain in the chest which can only be relieved by narcotics. Since the continued use of these drugs may lead to addiction, it is a wise practice for a physician, in prescribing the cough mixture or directly administering codeine, morphine, veronal, or similar products, to diminish the dose gradually, omit the drug occasionally, and finally leave it out of the cough mixture entirely, or replace the morphine, codeine, or veronal tablets by tablets made of substances of a more innocent character. For example, a cough mixture made of syrup of wild cherry or of Virginia prunes, with syrup of tolu, will taste just the same whether or not it contains the narcotic. Such little deceptions may sometimes be necessary in private as well as in hospital and sanatorium practice. Purely nervous anorexia may also be combated in a similar way by giving an innocent tonic.

The dietetic directions for a bed patient must of course be given to the nurse, and to the ambulant case they should preferably be given in writing. In his anxiety to gain weight the patient must be guarded against stuffing which is not productive of either physical or mental rest.

To assure rest of body, mind, and soul, the patient should be asked directly if he has any mental anxiety, and if it is within the power of the physician to remove it, he should endeavor to do so. If he worries on account of financial matters, the relatives should be informed of it so that steps for relief may be taken. The patient who worries will not eat well, and his recovery will be inevitably retarded thereby. Worry and anxiety are among the greatest obstacles to the successful treatment of tuberculosis, particularly among the poor, when the patient is the breadwinner of the family. Doomed to temporary inactivity, as otherwise he cannot be restored to health, he usually broods over his fate and worries about how those who are dependent upon him will get along. As already suggested, wherever the relatives are in a position to relieve the patient of financial worry, they should strive to do so, but when the relatives themselves are poor, of course no relief can be expected from them. The wonderful results obtained by Dr. Pratt, of Boston, were doubtless due to the fact that with the aid of funds placed at his disposal by the Emmanuel Church, he was enabled not only to take the very best of care of a large number of his tuberculous poor by installing the sanatorium treatment in their own homes, but he could investigate the financial resources of all the patients under his care, and when there was want, the good men and women of the church supplied food, clothing, and other necessities of life for the family so that the patient could feel absolutely sure that those who were dependent upon him were amply provided for. To appreciate this phase of psychology in the treatment of the consumptive, one must have observed the psychological change in a patient who was suddenly relieved from anxiety concerning his loved ones by the assurance that all was well at home and that there was no suffering or want. It is not to be wondered at that the results obtained by Dr. Pratt equalled, and in some instances surpassed, the best results obtained in sanatoria for the consumptive poor located in almost ideal climatic regions. Here is a field where public and private philanthropy can do immeasurable good.

We have already referred to how to prepare the patient's mind for a possible hemoptysis. Mental and physical quiet is of course all essential during the period of bleeding of the lung, and during an active hemoptysis an injection of morphine is certainly the ideal remedy—the "G. O. M." (God's Own Medicine) as the great Osler used to call it.

Artificial pneumothorax is of course the ideal remedy if it can be determined whether the hemorrhage comes from the right or left lung, and if pleuritic adhesions do not prevent entrance into the intrapleural space. If this is impossible, of course ligation of the extremities becomes necessary. The sight of a great deal of blood always alarms the patient and often those who observe it. In ward service the bed of a patient with a serious hemorrhage should be surrounded by a screen so that his fellow patients may not observe the bleeding.

In the course of the disease the patient may at times have a chill. This should of course be treated like any other chill by hot drinks and external warm applications, unless it is of a malarial character. Here, however, I wish to say that in all our aerotherapeutic measures we should try to avoid chilling the patient, and I am thoroughly opposed to treating the advanced case in the open air on cold days. If the environment is so cold that the patient feels chilly, uncomfortable, and unhappy, the cold aerotherapy will probably do him more harm than good.

We have above defended the average tuberculous patient against the accusation of being a psychoneurotic. Nevertheless that sometimes in the moderately or far advanced stages, where the symptoms are painful, the mind may be influenced thereby is selfevident, but this is by no means characteristic of tuberculosis but common to all serious diseases.

Whether the pain is real or not, the physician should listen sympathetically to the complaint of the patient even if inwardly convinced that the trouble is imaginary or greatly exaggerated in the patient's recital. Nothing is gained by disputing the patient's claim that he suffers, but he may be told that the trouble is probably of a nervous origin and will pass away as soon as he is quiet. The sympathy of his medical adviser will have a beneficial psychological effect.

If the patient is actually suffering, he should, of course, be given relief by medicinal agents. If, in the opinion of the physician, the pain is only imaginary, some innocent mixture may be given, and if in addition the patient's mind can be diverted to other things by rest breathing, autosuggestion, or prayer, it will surely be a benefit to the sufferer.

The reading of good but not exciting books to the patient or by the patient himself will help to pass the time pleasantly and lead the invalid's thoughts away from his disease. When the patient is of a religious nature, the cooperation of the minister of his church is often most helpful to overcome despondency and restore a hopeful outlook to the discouraged sufferer.

Nervous and digestive disturbances, or excess of sexual excitation, must of course be attended to by hygienic, dietetic, and sometimes medicinal means, for if neglected they are apt to interfere materially with the physical as well as the mental rest of the pulmonary invalid. However, I hope I may once for all disabuse the minds of the lay as well as some of the medical world who hold the tubercle bacillus responsible for making the consumptive more sexually active than he was prior to the development of the disease. The fact of the matter is that the enforced idleness of the tuberculous patient and the foolish administration of large quantities of eggs are responsible for finding once in a while a distinct venery in a tuberculous sufferer. To divert the mind into other channels and encourage selfcontrol are the remedies for this occasional phenomenon. Good, sweet and soothing music, performed by the artist in person before the patient, or by graphophone or radio, will always be a good adjuvant in the treatment of the nervous, depressed or discouraged tuberculous patient, as it is a good remedy for almost any kind of patient.

(To be continued)

The Secundines in Relation to Fetal Pathology

H. D. FAIR, M. D.
Muncie, Ind.

In this paper the term secundines is used in its literal interpretation. The word is derived from the Latin *secundus,* meaning, to follow: therefore in my usage it will include all the uterine contents which naturally follow the fetus when it makes its egress from the mother's womb. These consist of four items, viz., amniotic fluid, umbilical cord, placenta, and membranous sac.

The conclusions I have drawn are based largely on my own experience, consequently, with the exception of a few undisputed statistical facts, no socalled authority can be held accountable for any assertions which I may make.

AMNIOTIC FLUID

The amniotic fluid, so essential to the development of a perfect fetus, is not stable either in composition, color, density or amount, ranging in specific gravity from 1,010 to 1,070; in color from pale amber to deep bronze, and in opaqueness from slight flocculence to a dense meconium or bilelike consistency. Where the amniotic fluid comes from has been a subject of controversy for hundreds of years. While it contains some of the matter found in normal urine it is not likely that much of it comes from the fetal kidneys.

DeLee says that there is usually less fluid in the amniotic sac at the completion of term than there was at the seventh month of gestation. Now, if it were true that the fetus urinated it would undoubtedly pass a greater quantity during the ninth month than during any previous thirty days, and DeLee's dictum would not hold good.

It has been demonstrated, by the presence of lanugo, epidermic cells, etc., in the fetal stomach, that it swallows a portion of its amniotic surroundings. If this is true it is hardly likely that nature would design or intend a fetus to swallow its own excretion which is largely toxic.

I have examined several specimens of normal color and low specific gravity and found the composition to resemble that of normal perspiration from the adult—even to taste. The following substances have been found in normal amniotic fluids: albumin, calcium carbonate, calcium phosphate, diastase ferment, epithelial cells, leucocytes, meconium, pepsin, potassium bicarbonate, potassium sulphate, sebaceous matter, sodium carbonate, sodium chloride, sodium phosphate, sugar and other elements. The normal amniotic fluid holds many of the constituents of blood serum which are probably secreted by the mother in some way. In the *American Text Book of Obstetrics* I find this assertion, "Hydramnios may be due to oversecretion, imperfect absorption or to a combination of these." But we are left in the dark as to just what organs or tissues furnish the secretion or which perform the absorption.

Sometimes the fluid decomposes. While this condition is usually coincident with death and putrefaction of the fetus, it is not always so.

I believe that a fetus may urinate, but when it does, that the act is merely incidental or accidental. It is possible that under certain conditions it may swallow a gulp of amniotic fluid, but this contains no essential nourishment and the ingestion was unintended. If amniotic fluid does get into the fetal stomach it seems more likely that it trickled down the esophagus instead of being swallowed.

It is possible that if the circulation rate of the mother be increased or if she have a temporary elevation of temperature, the sweat glands of the fetus may become active, and perspiration from its body mingles with the fluid, yet I believe also that the bulk of the fluid is secreted by or through the amnion itself. I will have more to say regarding this point later.

The quantity of amniotic fluid has varied, in my experience, from an imperceptible amount up to approximately four gallons. I have collected and measured the quantity on several occasions where a quantity above normal was suspected, and in every instance where there was more than three quarts of fluid there was also some pathology to be found in the fetus.

In the instance above mentioned where the quantity was four gallons the fetus had a marked exophthalmus, and the thyroid gland was greatly enlarged. During the final expulsive effort he inspirated some of the fluid and strangled. Probably it was well that he did so.

Hydrocephalus, spina bifida, anencephalus, ascites and syphilitic edema are the usual accompaniments of hydramnios, for which either the fetus or the mother must be responsible. Hydramnios is a real factor in uterine inertia. The uterus may become so distended that the muscles have completely lost their tone. The treatment is obvious. The other extreme known as oligohydramnios, although less frequent, is just as serious a condition as an excess, and may be responsible for club feet or hands, wry neck, spinal curvature, ankylosis of joints and even abrasions of the skin on prominent parts such as the shoulders or trochanters, with possible adhesions to the amnion.

UMBILICAL CORD

Variations in the umbilical cord are decidedly interesting to one who is observant of details. Occasionally a specimen is really marvelous. The shortest cord I ever saw had a length of nine inches and the longest fifty-five inches. Some are frail in structure and small in caliber, and contain no twists. Others are tortuous and irregular in outline, massive in size, containing superfluous and often unequally distributed amounts of Wharton's jelly. Some are unsightly, some are beautiful. One of the most remarkable of these was perfect in anatomical content and relationship. Torsions ran the whole length (twenty-two inches) and were as regular and similar, one to the other, as the coils of a steel shaving coming from the tool of a machinist's lathe.

It is said that there may be no cord at all, the placenta being attached to the fetal umbilicus. I never

saw such a one. I have never encountered one so actually short as to interfere with delivery, although I frequently contended with problems due to a relative shortening that made the task difficult.

Coils of cord around the fetal neck are common and seldom of serious consequence, but they may involve an extremity or part, constricting and interfering with development to the extent that permanent deformity or uselessness results.

Other abnormalities which are encountered are rupture of a varix (hematoma), cysts, apparently resulting from liquefaction of the jelly, faulty insertion at the placenta, or knotting sufficient to cut off the blood supply, thereby causing the death of the fetus. I have one specimen showing one double and three single knots tightly drawn. It is probably unnecessary to add that the fetus attached to this cord met a premature death and birth.

On one occasion a woman miscarried when she was between the fourth and fifth months of gestation. Inspection showed that the fetus had been dead several days; death evidently due to constriction caused by three complete coils of cord which encircled the neck.

THE PLACENTA

It is remarkable how much information an obstetrician may miss if he presumes that all placentæ are very much alike and neglects to give each a careful scrutiny, for in nearly every instance where a fetus with normal parentage shows some lack in nutrition or function there will be found an abnormality of the placenta.

In the large majority of normal cases the weight of the placenta will approximate one sixth that of the fetus. The most common cause of or association with overweight is syphilis, which can be recognized frequently in the placenta when there is no immediate manifestation in the fetus. This is such a common and well known condition that I pass it without further comment.

The most frequent pathological condition encountered in the general run of placentæ is the presence of infarcts. These may be of the white or red type, and are either meagre or profuse in number, minute or of large size, of much or of little importance.

In October of this year a woman, pregnant for the second time, placed herself under my care. She was somewhat despondent, for three years ago she had a premature labor at about the eighth month. She reported that perceptible fetal movements had ceased about two days before labor had begun, and that the fetus survived only a few hours following delivery.

At the time she consulted me she was advanced seven and one half months, and complained that the fetal movements were becoming weaker each day for the past week. Both she and her husband were above medium stature and appeared to be in excellent health. Bodily functions were more nearly normal in this patient than is usual in pregnant women. She was of the type whom we would expect to bring forth infants weighing eight or nine pounds. A careful examination failed to bring to light anything out of the ordinary, either historical or clinical, so I prescribed a supply of Schuessler's calcium phosphate, following which the fetus became more active, and the patient's mood more optimistic.

She went on to the estimated date of confinement, and dilatation was complete relatively early in labor, but the fetal head maintained its position midway in the cavity of the pelvis in spite of good pains and a left occipitoanterior presentation. After a reasonable wait in which no progress was made I applied forceps and delivered a scrawny six pound baby, showing a considerable degree of malnutrition. The cord was small, friable and stringy. Wharton's jelly appeared only in faint traces. One cotyledon near the centre of the placenta had undergone entire infarction. On a lateral periphery many small infarcts appeared. At a chance guess I would say that not more than one half of the placental surface was functioning.

Hemorrhage into the placenta is sometimes produced by congestion of the uteroplacental vessels, due to disturbances in the mother's vascular system. The extravasation may be intraplacental, into the uterine sinuses or more frequently into the decidua serotina, giving rise to the condition sometimes designated as placental apoplexy. Placental hematomata are encountered fresh, or the coagulated blood may be found in various stages of disintegration. The stagnant blood usually experiences the retrogressive metamorphoses, or may undergo cystic, fatty or calcareous degeneration. The pressure upon the villi produced by the hematoma always impairs the nutrition of the fetus.

I have observed at least a fifty per cent. increase in placental hematoma with partial separation of an anteriorly situated placenta since the popularity of osteopathy has become established. You may take this averment for what it is worth, draw your own conclusion and make your own application.

On the whole, the clinical importance of placental anomalies, in so far as form and arrangement are concerned, is not great. A wide variation is possible without pathological results. In case of accessory tissue, however, portions may be retained in the uterus giving rise to post partum hemorrhage, subinvolution or sapremia.

When the form and arrangement of the placental cotyledons vary from normal we often find a unique insertion of the cord whose vein and arteries may be bare and exposed for one or more inches. Levret has pointed out that in marginal insertion of the cord the attachment was always to the edge nearest the os uteri. Barnes verified this.

THE FETAL ENVELOPE

Twenty-eight years ago I prepared, and the *Clinic* published, a case report entitled A Double Amniotic Sac. The report caused more controversy and discussion than anything else that I have ever written. In addition to personal letters received from here and there, several columns of the *Clinic* were devoted to comments sent in by various readers. One writer contended that I did not have a double amniotic sac—that the first fluid lost by my patient was chorionic and that the second only was amniotic. I have since decided that he was correct, for on several occasions I have found a material separation of the two membranes over various areas, and the resultant space filled with fluid.

Once when inducing labor at the thirty-eighth week, because of a contracted pelvis in an elderly

primipara, I punctured a membrane, and after the escape of a few ounces of fluid, felt another sac come down and take its place over the dilated os. This also was punctured and the scalp presented. It appeared that these membranes had been separated one half or three fourths of an inch.

Our anatomists tell us that, early in embryonic life, the amnion expands until its outer surface comes in contact with the inner layer of the chorion, and this relation continues throughout gestation; more or less fusion occurring between the opposing surfaces.

Now, if it be difficult to determine the source of the fluid formed within the amniotic sac it would appear more perplexing to solve the problem of the origin of the fluid between the amnion and the chorion. The fact that it *is* there first led me to conclude that the amnion has a secretory power and function. Perhaps the constant friction between the outer and inner layers which occurs with the rhythmic contractions of the normal gravid uterus may stimulate the secretion of a fluid on the same principle that a serum laden blister may come on the palm of a novice following the vigorous use of a pick or shovel.

Referring back to Dr. DeLee's assertion—he does not tell us why there is less fluid in the sac at the seventh than at the ninth month of gestation. May I venture an explanation?

In embryonic and early fetal life the chorion is vascular. As development progresses this vascularity becomes less and less until at the seventh month of gestation about the only source of blood supply is at or near the placental margin. After the seventh month of gestation nourishment must be accomplished either by continuity of structure or by fluid contact as in certain parts of the eye.

Early in gestation, because of ample vascularity, this fluid between the chorion and amnion is abundant and after it performs its nutritive function finds its way into the cavity of the amniotic sac. Later, because of the lack of general vascularity, the fluid secreted becomes so meagre that there is no surplus left after the membranes get the nourishment necessary for their continued existence in a functionable form.

You may consider this theory far fetched but I believe it worthy of consideration.

Some ten years ago I became curious to know why the amniotic sac would rupture spontaneously at or near the expected time of labor, but before labor pains had begun. In other words, why would the first premonition of impending labor be a sudden gush of fluid? In one particular instance the woman was reclining at midafternoon on a comfortable couch.

I propounded this question to four noted obstetricians with whom I had a slight acquaintance. A replied by saying that the phenomenon usually occurred when the presentation was faulty, transverse or breech predominating. B said it was due to continued pressure on a particular area after the position of the fetus became fixed. C thought that the membranes might become adherent and unable to "give" when the stress of expansion was exerted, therefore tore as a result. Dr. Paul Titus, of Pittsburgh, believed that early rupture was because of innate imperfection in the membrane itself.

In reviewing these replies briefly, it stands to reason that that premature rupture occurring *after* one or more really vigorous pain would point to a malpresentation or position, but I could not accept A's answer as correct.

B's explanation was not satisfactory either. I thought there should not be "continuous pressure" of any consequence before a woman was conscious of contractions of the uterus. C's answer would undoubtedly hold good in a small percentage of cases, but, of course, not all.

The opinion of Dr. Titus seemed to be the most reasonable, so I began to observe more closely as opportunity presented and I now believe his theory to be applicable in the greater number of cases for both the amnion and chorion are likely to undergo several changes in consistency during the progress of gestation.

We have already referred to adhesions involving the fetus in oligohydramnios. The adherent amnion may thicken and form a band or bands that become sufficiently strong to exercise a constriction that will sever an arm or leg.

Just why the infant who emerges with part of his envelope still covering his face (born with a "veil," as the laity put it) is supposed to be lucky and have prophetic ability, I do not know. The fact that he is alive may prove his luck, for the pocket of membrane covering his head may contain enough fluid to strangle him should he make an attempt to inspire.

There are instances on record where the entire contents of the uterus have been expelled in a mass with the sac intact. I had one interesting experience. A colored woman, mother of four children, was at the eighth month of gestation. She came to me because she felt that something was not right, and I decided that she was carrying a dead fetus. Sure enough, three days after I saw her she went into labor. There was no distinction between the second and third stages, for the entire uterine contents were expelled in the unruptured sac which contained about two quarts of decomposed fluid. The fetus (five pounds) was macerated, yet the sac lacked none of its original toughness. I have never seen this happen with a live baby at full term.

You will observe that I have not mentioned placenta previa; nor have I referred to the various molar pregnancies. The former condition was ignored because a normal placenta may have many abnormal implantations without being responsible for fetal pathology. In the latter condition, while molar degeneration is due, in most instances, to anomalies of the chorion, proliferation of the syncytium, it usually occurs so early in gestation that, if the process continues for any length of time, all traces of the embryo or fetus disappear; consequently that which has no existence has no pathology. Once in a while the symptoms develop late in pregnancy and, where only part of the chorion is involved a living infant may be born, but such a result is so rare that it is good practice to empty the uterus so soon as a diagnosis of hydatidiform mole is made.

We may naturally inquire, what can we do, when confronted by an abnormality of the amnion, to make the prognosis for the fetus more favorable? In the presence of hydramnios we may be able to make a diagnosis of syphilis, anemia, heart or kid-

ney disease, and if so, treat it the best we can. The benefit accruing to the fetus is questionable because we cannot always be certain how long the fetal pathology has existed, if present, nor how much damage has already been done.

Hydramnious may, instead of a causative factor, be a sequence of monstrous conception. It is safe to say that they are frequently concomitant. In three cases of oligohydramnios, recognized between the sixth and eighth month of gestation, where no pathology was found, I got good results from the use of zanthoxylum (prickly ash), two doses a day up to a short time before delivery. Increase of fluid lessens the probability of fetal deformities.

I want to urge once more—get your patients under your observation and care early in their term of gestation.

Disease of the placenta may be responsible for improper nourishment and development, and at times the death of the fetus. If the fetus survives, the increased resistance encountered by the placental circulation may have produced disease of the heart or of some other viscera. There are no known methods whereby placental disease or anomalies, other than placenta previa, may be recognized *in utero*.

132 West Jackson Street.

Irradiation of Diseased Tonsils

J. COLEMAN SCAL, M.D.

New York

In 1924 (1), and again something over a year ago (2) I published reports of work accomplished in the application of radium to pathological conditions of tonsils, which were, for various reasons, not amenable to surgical removal. While tonsillectomy still remains the method of choice in all cases where it can be satisfactorily and safely performed, there are many conditions where it is ruled out. In cardiac, pancreatic or kidney disease, for example, or hemophilia, any operative procedure is out of the question, and we also frequently encounter patients in whom advanced age or general weakness makes it unwise to subject them to the shock of operation, even when it is so slight as that induced by a skilfully performed tonsillectomy. Then again, there is that not to be ignored minority who positively refuse operation—usually because of fear. To the large group made up from the classes just enumerated radium application offers a satisfactory alternative, and one the results of my work fully indicate is bound to become of constantly increasing importance as the technic of radium application is improved and perfected.

In my first series of seven cases radium applications were made by means of needles. A ten milligram radium needle was inserted into each tonsil and allowed to remain there for three hours, the treatment being repeated five times thereafter at intervals of two to three weeks. The effect of this treatment was decidedly beneficial, but the insertion of the needles caused considerable pain and gagging to all the patients, and in not a few instances was followed by a general systemic reaction lasting for several days.

In the second series, which brought the whole number of cases up to thirty-two, the implantation of bare tubes of radium emanation was the method employed. Following this the results were much more satisfactory than by the needle method. Not only did we obtain complete radiation of the affected lymphoid tissue (in some of the needled cases the lower poles did not receive any radiation at all), but the implantation produced neither pain nor gagging, and the resulting reaction was trifling. The serious drawbacks to this procedure were the unavoidable production of necrosis about each unscreened tube, which, though small, was yet enough to produce the reactions noted, and the fact that the tubes could not be recovered, but remained in the tissue as foreign bodies. The results, however, were so uniformly good as to leave no doubt that in the implantation of radium emanation we have found a highly efficient method of dealing with inoperable disease of the tonsils.

I am now able to report a series of twelve additional cases treated with radium by still another method—the implantation of removable platinum-radon seeds. This technic was recently perfected by Dr. Joseph Muir, who conceived the idea of screening the seed and making it possible to remove it after it had done its work, as well as designed instruments nicely adapted for placing the seeds, and withdrawing them when the desired period of radiation is completed. This method has many advantages over anything which has heretofore been put forward. Instead of a number of radioactive centres—three needles, or three or four unscreened seeds to each tonsil—a single removable seed is all that is necessary on either side, the platinum screenage permitting the radium content of each tube to be great enough to provide radiation sufficient to affect all the tissue equally, while at the same time it absolutely prevents necrosis.

The technic of implantation is so simple that it can be done by the laryngologist unassisted, although of course, if trained aid is to be had, it is highly desirable, especially in the presence of submerged tonsils, as such must be brought into view by being drawn out with a suitable forceps before the implantation it attempted.

TECHNIC

The Muir radon seed implanter is shown in Fig. 1. The trocar is needle pointed, this point being so fine as to cause but little trauma to the tissues. The trocar D is passed through the lumen of the implanter, and the removable platinum radon seed E is placed in the loading slot at G. The sliding spring C is then advanced until it holds the seed in place, pressed down upon the shaft of the trocar. The centre of the mass of tonsillar tissue having been ascertained, the opera-

tor inserts the point of the trocar exerting pressure with the index finger as shown in Fig. 2. The point enters to a depth of one centimetre, being stopped at this point by the shoulder of the implanter, as indicated at J. As soon as the tissue is pierced the trocar is withdrawn, as shown in Fig. 3, whereupon the seed

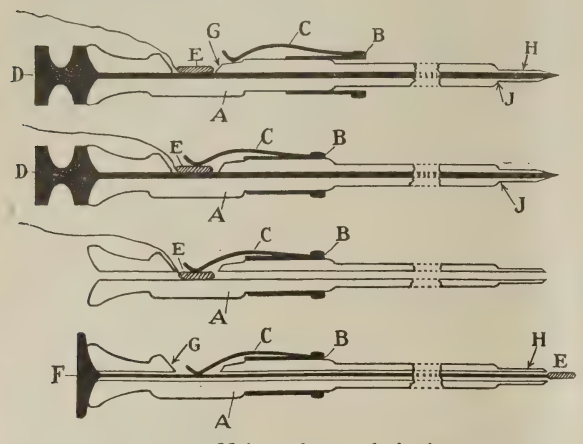

Fig. 1.—Muir radon seed implanter.

drops into the vacant lumen of the implanter, and on insertion of the obturator F, is pushed down the channel until it is deposited in the tissues of the tonsil as shown in Fig. 4. The obturator is then withdrawn together with the instrument itself, leaving the seed implanted at a distance of one centimetre from the point of entry, with the attached thread—previously cut off to a length of two centimetres—pro-

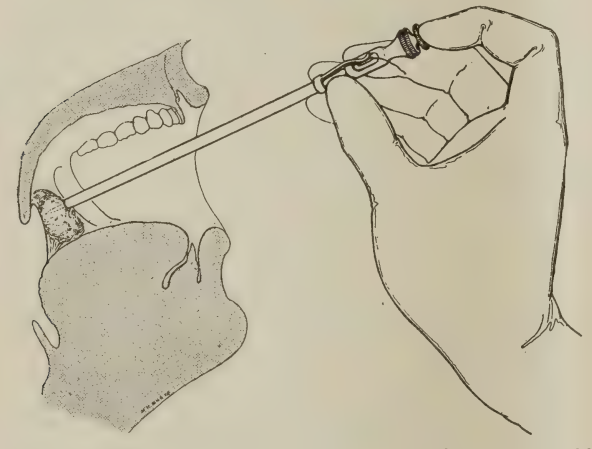

Fig. 2.—Point of trocar inserted, operator exerting pressure with index finger.

truding from the point of entry. This one centimetre length of thread hanging down over the surface of the tonsil does not cause the patient the slightest inconvenience, nor does it interfere in any way with function.

The seeds are permitted to remain in position for a period of four days. At the expiration of this period they are pulled out by means of an ordinary forceps which readily grasps the length of thread left protruding from the point of entry. As the pain of insertion and removal is practically *nil,* at no time is any anesthetic required, and there is, of course, no hospitalization, nor disability of any kind.

THE EMPLOYMENT OF PLATINUM RADON SEEDS

Case I.—S. P., female, aged forty-five years (referred by Dr. A. L. Ringer). For the past six years sore throat and joint pains, which kept her indoors, sometimes for long periods. Under Dr. Ringer's treatment on account of diabetes, for the past year. On examination her tonsils were inflamed and hypertrophied, and crypts were in evidence from which seropus could be pressed out. Patient so weak assistance in walking was necessary.

Removable platinum radon seeds containing approximately 2.82 millicures of radium emanation were implanted one on each side. Seeds removed at the end of four days by means of attached thread. No reaction and patient much improved at next examina-

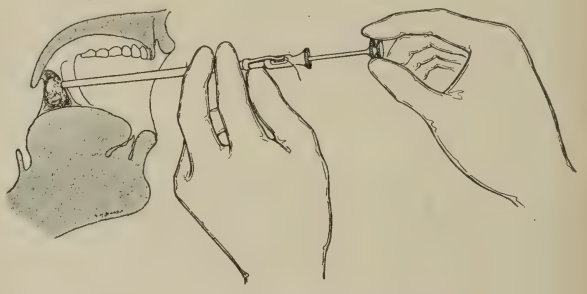

Fig. 3.—Showing trocar withdrawn.

tion. In three weeks could get about unassisted, and although the joint symptoms have not entirely disappeared, the sore throat has been eliminated, and the general condition is greatly benefited. The tonsils have gradually atrophied leaving only fibrous tissue. The patient is still under observation.

Case II.—M. G., male, aged fifty-four years. For the past six years frequent attacks of sore throat with increasing deafness; also complaint of fleeting pains in the joints. Tonsils moderately enlarged and diseased, showing follicles which contained pus. Beginning otosclerosis on both sides, with diminished hearing. In each tonsil a 2.8 millicurie platinum radon seed was implanted and withdrawn on the fourth day. There was no reaction of any sort, the tonsils gradually atrophying. There have been no more attacks

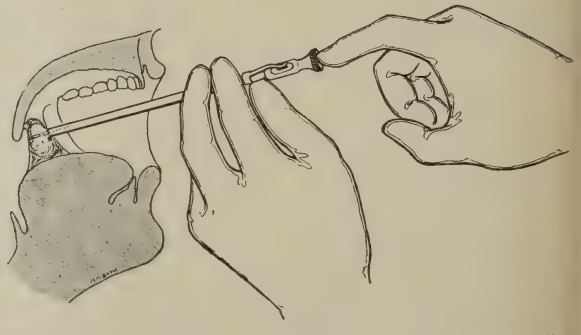

Fig. 4.—Showing radon seeds deposited in tissues of tonsil.

or tonsillitis and the joint pains are seldom experienced. No improvement in hearing.

Case III.—J. H., male, printer by trade, aged fifty-two years (referred by the Medical Department of the Workman's Circle). History of repeated at-

tacks of tonsillitis which confined him to bed for several days at a time. Operation refused because of fear. Examination showed the tonsils to be so hypertrophied as to meet in the centre of the pharynx, causing the patient to talk "as though he had a hot potato in his mouth." A 2.81 mc. platinum radon seed was placed on each side in the usual manner and taken out on the fifth day. There was absolutely no reaction and gradual atrophy of the tonsils took place until only fibrous tissue now remains. No further attacks of tonsillitis.

Case IV.—R. P., female, aged fifty-three. She had typhoid fever as a child, and was operated six years ago for removal of appendix and fallopian tubes. For twelve years past there has been almost continuous sore throat, associated with rheumatic pains. Examination shows that though only moderately enlarged, the tonsils are greatly diseased, for the pillars are red and adherent and pus could be expressed from the left tonsil upon pressure. There was also a myocarditis present. The treatment consisted in the implantation of a removable platinum radon seed into each tonsil; content 2.66 mc. These seeds were withdrawn after four days with no reaction at any time. Four weeks later the patient returned saying her throat was no longer sore, pain in extremities had ceased and she felt better generally. The tonsils had at this time atrophied considerably, and the large pus containing crypt originally visible on the left side has gradually closed up and disappeared.

Case V.—I. C., a rabbi, aged sixty. The complaint was sore throat, especially noticeable after singing. Examination revealed diseased tonsils, very much enlarged, from which cheesy material could be expressed. There were no joint symptoms. Two removable platinum radon seeds were implanted and kept in position for four days. This procedure induced no reaction, and there has been no further complaint of sore throat. The tonsils atrophied so greatly that at the end of a month they had decreased in size at least fifty per cent. This patient is still under observation.

Case VI.—T. P., female, aged sixty; referred for tonsillectomy for the relief of joint symptoms. She gave a history of sore throat so severe as to prevent her from performing her household duties. Examination showed the tonsils to be submerged and very red and diseased. Seropus could be expressed on both sides. A platinum radon seed in each tonsil, placed in the usual way, and initially containing 2.62 mc. of radium emanation, produced no reaction, and was removed at the end of the four day period. Two months afterward the patient was practically without joint symptoms, while the size of the tonsils was appreciably diminished. At the end of four months the tonsils could be made out only after the anterior pillars were retracted. This patient also is being kept under observation.

Case VII.—J. C., male, aged thirty-seven, gave a history of repeated attacks of tonsillitis; his tonsils were submerged and cryptic. A 2.5 millicurie seed was placed on either side and removed at the end of four days. Within two weeks there was a noticeable regression of both lymphoid masses, and within six months the inflammation was a thing of the past. The tonsils are now entirely atrophied.

Case VIII.—K. S., female, a professional singer, aged twenty-three. She had suffered severe and prolonged attacks of tonsillitis for a number of years, these illnesses seriously interfering with her professional activities. A 2.5 millicurie platinum radon seed was implanted in each tonsil and withdrawn at the end of the four day period. There have been no more attacks of tonsillitis, and at the end of two months the tonsils had almost entirely disappeared. When seven months had passed only fibrous tissue could be seen and this was only just visible.

Case IX.—J. S., male, aged fifty. This man gave a history of numerous disabling attacks of tonsillitis, and of arthritic symptoms. Tonsils pedunculated, and so hypertrophied as to meet at the median line. The dose consisted of a 2.8 platinum radon seed on either side, withdrawn after four days. A noticeable disappearance of the tonsils commenced within four weeks, and after a lapse of six months there has been no return of any of the symptoms.

Case X.—J. B. T., male, aged forty-seven. This patient was a hemophiliac, giving a history of excessive bleeding upon the slightest trauma. His tonsils were submerged and cryptic, and he had often been advised to have tonsillectomy done, but had been restrained by fear of hemorrhage. A dose of 2.5 millicuries on each side for the four day period brought about complete regression of the tonsillar masses within a few months.

Case XI.—C. W., physician's wife, aged thirty-three. She had suffered repeated attacks of tonsillitis, and on examination the tonsils were found to be pedunculated and largely converted into masses of fibrous tissue, the result of repeated inflammations. Though tonsils of this type are more difficult to effect by radiation, the placing of a 2.5 millicurie seed in each mass sufficed to cause their complete disappearance. Since the implantation this patient has been entirely well.

Case XII.—J. R., female, aged forty-five. This woman had an exophthalmic goitre and presented the typical Graves's syndrome. The tonsils were pedunculated and much hypertrophied. A 2.8 millicurie seed was implanted in each tonsil and removed from the mass at the end of four days. This was eventually followed, not only by complete regression of the tonsils, but also by a marked reduction in all the varied manifestations characteristic of the Graves's syndrome. The goitre was later radiated by a similar technic, with marked success.

CONCLUSIONS

In the implantation of removable platinum radon seeds we at present have an adequate substitute for tonsillectomy in those cases where surgery is, for any reason, contraindicated.

1. The amount of radiation can be measured with accuracy and the applicators located with such exactness as to insure equal and complete distribution throughout the tissues.

2. Only one treatment is necessary, a fact much appreciated by the patient.

3. The platinum filtration eliminates all danger of necrosis with subsequent sloughing of the tissue, systemic reactions of any kind never occurring.

4. The attached thread, making the seed easily removable when its period of usefulness is completed,

does away with the objectionable foreign body remaining permanently in the tissues—a drawback of the bare tube method.

5. There is no hospitalization, nor disability of any kind. No anesthetic is necessary, yet there is no pain, nor suffering of any description. The complete absence of shock is a great advantage in those cases classed as inoperable.

The Use of Vaccines and Sera in Communicable Diseases*

RALPH OAKLEY CLOCK, M.D., F.A.C.P.

Pearl River, New York

(*Concluded from page* 598)

TYPHOID FEVER

Typhoid vaccination is particularly indicated for the many thousands who annually leave their homes for travel or life in the country where the sources of water, milk and food supplies are apt to be uncertain; for campers, lumbermen, civil engineers' forces, and industrial concerns that employ a large number of people; and for nurses, house staffs and administration staffs of hospitals.

Vaccination against typhoid fever is now a procedure of established worth, for there is no question of its power to prevent infection. The duration of immunity is difficult to establish, but it seems to be at least two years. Much depends on the amount of exposure. The protection is not absolute; but while some cases do occur among the vaccinated, the number is small.

Kinds of vaccine.—Originally, vaccination against typhoid fever was carried out with a vaccine prepared only from the Rawlings culture of the typhoid bacillus. To protect against the unusual exposure to typhoid infections due to mobilization of an army and navy for warfare, a combined vaccine prepared from the typhoid bacillus and from paratyphoid A and B bacilli was adopted by the medical departments of the United States Army and Navy during the World War; and such a triple or combined vaccine has been quite universally employed in civilian practice.

However, experience has shown that exposure to paratyphoid infection is infrequently encountered, except in the Southern States; and that the triple vaccine gives more frequent and more severe reactions than does the plain typhoid vaccine. Apparently, the paratyphoid bacilli develop toxic substances in the vaccine more provocative of severe reactions than the typhoid bacillus; for fewer severe reactions follow the use of a straight typhoid vaccine.

Accordingly, in January, 1925, the Medical Department of the United States Navy (12) adopted plain typhoid vaccine which represents essentially a reversion to the vaccine used prior to the War. A few months previously, the Surgeon General's Office of the War Department ordered a reduction in the strength of the triple vaccine made at the Army Medical School.

Reactions avoidable.—In view of these facts, the plain typhoid vaccine is now being recommended for general civilian use. However, it should be pointed out that reactions are largely avoidable; because there is nothing, except a matter of convenience, which prohibits giving a greater number of smaller doses instead of the total amount of vaccine in three doses. In fact, there is distinct evidence that the standard amount given in more and smaller doses would give greater immunity. This is indicated by the results obtained by immunizing laboratory animals. The use, therefore, of the standard amount of typhoid vaccines administered in five doses at intervals of about five days favors the development of a greater degree of immunity and, at the same time, tends to minimize or even eliminate reactions.

WHOOPING COUGH

As a cause of death in children, whooping cough ranks fourth among the acute communicable diseases. However, if we could go behind mortality statistics and ascertain how many of the deaths attributed to pneumonia were a sequence to whooping cough, we would then realize that this disease constitutes a much more serious peril to children than is commonly known and recognized even by physicians.

The teaching that vaccines offer nothing of value is unfortunate, for it is not entirely correct. Such teaching discourages the laity from seeking medical assistance, and the result is that whooping cough patients run at large to a degree that constitutes a serious menace to the children of the community. In the vast majority of cases, because of the absence of fever and also because there is no such disability as febrile diseases generally produce, parents allow their child to roam about and to mingle with others. In this, unfortunately, they are sometimes encouraged by physicians. Moreover, many parents do not call in a physician when the presence of whooping cough in their child becomes evident. The disease may be either unusually mild or lack the telltale whoop or vomiting. This type of case is often overlooked by the physician, and such masked cases may prove more potent in spreading infection than the typical and severe cases.

*Lecture delivered at the New England Health Institute in Concord, N. H., held September 27 to October 1, 1926, under the auspices of the United States Public Health Service, the New England State Health Departments, the Yale and Harvard Schools of Public Health, and the Departments of Public Health and Biology of the Massachusetts Institute of Technology and Simmons College.

Value of vaccines.—Bacterial vaccines for the prevention and treatment of whooping cough have been in more or less general use for the past fifteen years. From the very first, the published reports have stated that pertussis vaccine is a helpful therapeutic measure; the authors being of the opinion that the vaccine treatment lessens the severity of paroxysms and diminishes the vomiting, and some think it to have high prophylactic value. Many physicians of excellent judgment and long clinical experience find pertussis vaccine effective as a therapeutic agent in a considerable number of cases, especially the severe ones, if used early enough and in sufficiently large doses.

The majority of reports in recent years, especially from the United States, England, Italy, Japan and Denmark, confirm the statement that vaccines made from Bordet bacilli have a beneficial effect on whooping cough. For example, Miller, (14) formerly director of the Division of Communicable Diseases, Health Department of Akron, Ohio, summarizes as follows:

> Experience seems to show that sufficiently large doses of Bordet bacilli establish a positive immunity against whooping cough and check the spread of the disease in the public schools. Whooping cough vaccine is the only therapeutic measure worthy of consideration in the treatment of the disease. Failures are due entirely to insufficient, timid dosage at too long intervals. I believe that public health authorities are justified in promoting immunization against whooping cough just as they are urging immunization against typhoid fever.

Fresh vaccine.—Several writers have emphasized the necessity for using freshly prepared pertussis vaccine, and have pointed out that the clinical results are more definite when fresh vaccines are used. Thus, Huenekens (15) reports that pertussis vaccine from two to three months old, employed in large doses, immunizes in only twelve and a half per cent. of cases; while freshly prepared vaccine employed in the same dose produces evidence of immunity in ninety-four per cent. of cases. Again, Bloom advises the use of fresh vaccine: not exceeding one month old, and preferably not more than ten days old.

Deterioration.—Obviously, freshly prepared vaccines are not always obtainable. By the time they reach the physician, vaccines prepared by suspending the bacteria in physiological salt solution often consist chiefly of nonspecific products of autolysis: in other words, selfdigestion is brought about by the enzymes within the bacterial cell with consequent loss of the specific immunizing properties. Furthermore, since the usual method of killing the bacteria by heat must alter certain protein constituents of the bacterial cell, it is evident that saline vaccines cannot represent the full immunizing properties of the bacteria. Hence, the failure of such vaccines to uniformly produce an efficient immunity.

Glycerol vaccine.—Pertussis glycerol vaccine, however, insures the equivalent of a freshly prepared vaccine at all times. The use of glycerol as a preservative is not new. It has been successfully used to prevent deterioration in several biological products. By suspending the mass of Bordet bacilli in 66 2-3 per cent. glycerol, deterioration of the bacterial protein with its specific immunizing properties is prevented for a long period, (16). And since the vaccine is not heated, there are no protein changes due to partial heat coagulation. Therefore, when the physician cannot be assured of a freshly prepared vaccine, the use of pertussis glycerol vaccine is to be recommended. Such a vaccine possesses many advantages substantiated by physicians of repute who use it regularly and obtain clinical results which are uniformly satisfactory.

Administration.—Infants and young children tolerate the vaccine injections exceptionally well and, as a rule, the younger the child, the less probability of reaction. In fact, newborn babies tolerate without any ill effects the maximum immunizing dose which is used for older children. The vaccine should be injected subcutaneously into the buttocks or into the anterior abdominal wall in infants and young children; while the arm over the insertion of the deltoid muscle may be used in older children.

Dose.—For prophylaxis, three doses of the vaccine are given at intervals of three days; the first dose containing two billion and the second and third each four billion Bordet bacilli. For the treatment of whooping cough, an initial dose of one billion is followed by two billion, four billion, six billion, eight billion, etc.; the injections being given every other day as a rule, or daily if the case is severe.

Results.—Clinical reports show that when the vaccine is administered to children after exposure to whooping cough, it may be considered as probably from 85 to 90 per cent. efficient. In those who do contract whooping cough after vaccination, the disease is very mild. The effect of the vaccine in the treatment of the disease is shown by, 1, a diminution in the number and severity of the paroxysms; 2, lessened vomiting; 3, marked shortening in duration of the disease; and 4, absence of bronchopneumonia as a complication.

SERUM REACTIONS

No discussion of the use of sera in the treatment of disease would be complete without some reference to serum reactions and methods for their control and prevention. The injection of serum or antitoxin may be followed by reactions of three types which, however, bear no relation whatever to the therapeutic properties of the serum, but are due to the protein contained in the serum.

1. *Serum sickness.*—In approximately sixty per cent. of cases there develops a skin eruption, edema, enlargement of the lymph nodes, pain in the joints and rise in temperature. Most commonly, such symptoms appear from eight to twelve days after the serum injections. While it lasts, the condition is very annoying but not dangerous, and complete recovery has always followed symptomatic treatment.

2. *Thermal reaction.*—Either immediately or within an hour there may be a chill and a rise of temperature lasting about two hours. This type of reaction occurs in about forty per cent. of cases.

3. *Anaphylactoid reactions.*—About one in every twenty thousand primary injections of serum is followed very quickly by more or less alarming symptoms, comprising rapid and feeble pulse, nausea and a feeling of suffocation. Such symptoms are particularly apt to occur in those persons who suffer from asthma or hay fever. These symptoms are best treated by prompt hypodermic injection of one c.c. (sixteen minims) of epinephrine hydrochloride (1:1,000 solution) and 1/100 to 1/50 grain of atropinesulphate. A second injection of epinephrine hy-

drochloride may be given if the symptoms do not rapidly improve.

Second injections.—A few deaths from serum injections have been recorded: about one for every seventy thousand persons injected. These deaths, however, have occurred chiefly and perhaps wholely in cases of status lymphaticus and have resulted from the first injection of serum. The fear of repeating a serum injection because of having sensitized the patient is practically groundless, for there need be no fear in giving a second intramuscular or subcutaneous injection to any person who has not suffered severely from the first injection. The only difference in the effects from the two injections will be that the serum reaction will follow almost immediately after the second injection (accelerated reaction). If the second injection is given intravenously after a considerable lapse of time, it should be given even more slowly than the first. If it is necessary to give serum to asthmatic persons, it is well to give it in fractional doses: 0.1 c.c. every fifteen minutes will usually be tolerated without disagreeable effects.

Skin test.—The skin test, which has long been advocated for determining hypersensitiveness to serum, has proved to be unreliable; for tests carried out in the Willard Parker Hospital in New York City have shown no correlation between skin tests and serum reactions. In fact, in approximately ninety-four per cent. of patients who gave a positive skin test a systemic reaction did not develop when serum or antitoxin was injected.

Eye test.—Recent evidence, however, indicates that the eye test (17), is apparenty a more reliable criterion of the probability of serum reactions. This test, therefore, may be used for determining the presence of hypersensitiveness to horse serum. For this purpose a 1:10 dilution of serum or antitoxin is instilled into the conjunctival sac. If a severe conjunctival reaction occurs, it indicates that a serum reaction may be expected if any amount of serum or antitoxin is injected. (The conjunctival reaction may be neutralized by the instillation of epinephrine hydrochloride solution). This eye test is now recommended as the most reliable method of testing for hypersensitiveness to horse serum or antitoxic globulin.

Prevention of reactions.—For practical purposes, the preliminary eye test may be limited to those patients whose history of asthma or hay fever indicates that they will develop severe serum reactions. With such a history and evidences of hypersensitiveness as revealed by the eye test, the fractional administration of serum, starting with very small doses, may be successful in inducing some tolerance. For this purpose, doses of 0.1 c.c. may be given subcutaneously and increased every fifteen minutes or as rapidly as reactions permit.

SUMMARY

1. In the development of vaccines and sera, laboratory research and clinical observation should go hand in hand, each acting as a control on the other.

2. The universal application of toxin-antitoxin for immunizing all children of preschool and school ages would soon result in community protection from diphtheria.

3. Antimeningococcic serum should be injected by gravity into the spinal canal between the third and fourth lumbar vertebræ or into the lateral ventricles through the open fontanelle, so that it will come directly in contact with the meningococci.

4. While waiting for confirmation of the probable discoveries of Tunnicliff and Ferry, serum from convalescent measles patients must be depended upon for the prevention of measles. Doses of six to ten c.c. are usually sufficient to prevent the development of the disease in children who have been exposed less than five days to measles.

5. Prophylactic vaccination against pneumonia is particularly indicated for persons who are very susceptible to pneumonia and who suffer from repeated attacks of the disease, and for large groups of persons who are living together under abnormal conditions, such as recruits in time of war. Pneumococcus vaccine could probably also be used with benefit in the case of industrial workers who are constantly exposed to cold and wet.

All cases of Type I pneumococcus pneumonia should be treated as early as possible with Type I antipneumococcic serum, administered intravenously in doses of 100 c.c. and repeated every eight hours until symptoms indicate that the infection has been overcome.

The researches of Felton at Harvard University give promise of eventually placing the serum treatment of pneumonia on a more practical and efficient basis. His refined and concentrated solutions of the antibodies in antipneumococcic sera are now being subjected to clinical trials in several large cities.

6. The suspected rabid animal ought to be confined and kept under observation for one week, because, if the animal is in the incubation stage at the time of the biting, it will show symptoms of rabies and die within that period. However, the safest procedure is to begin antirabic treatment at once, without waiting for a positive diagnosis to be made from the animal.

The Semple method of rabies vaccine consists of a killed virus and possesses many advantages over other methods. It has largely superseded the older Pasteur method of treatment.

7. Persons susceptible to scarlet fever sometimes give a negative Dick test. This may be due to weak binding power of the toxin with the tissue cells or to sudden deterioration of the toxin.

The best dose of scarlet fever toxin for immunization has not yet been definitely established.

The rash in scarlet fever indicates the necessity for antitoxin treatment, while the extent of sepsis is the guide to the amount of antitoxin needed. The smallest or basic therapeutic dose should be an amount that will neutralize 600,000 standard skin test doses of toxin. Treatment should cause within twelve to eighteen hours, a marked subjective improvement, critical fall of temperature and pulse, and fading of the rash.

8. During 1925, the United States reported more smallpox than any other country except India. The many advantages of the puncture method of vaccination should appeal alike to the health officer, school physician and general practitioner.

9. The experience gained during the World War emphasized the immense value of antitoxin in the prevention of tetanus, and demonstrated the importance of freely cutting away all dead tissue within

and about extensively lacerated and contused wounds.

Extensive experience has proved that the intraspinal method of administering tetanus antitoxin should be given preference over all other methods. The dose recommended comprises five thousand to ten thousand units intraspinally and ten thousand units intravenously on the first day; five thousand to ten thousand units intraspinally on the second day; five thousand units intraspinally on the third day; and five thousand to ten thousand units subcutaneously on the fourth day.

10. Typhoid triple vaccine gives more frequent and more severe reactions than does the plain typhoid vaccine. Therefore, the plain typhoid vaccine is now recommended for general use. By giving the standard amount of vaccine in a greater number of small doses, reactions may be avoided.

11. The majority of reports in recent years confirm the statement that freshly prepared vaccines made from Bordet bacilli have a beneficial effect on whooping cough. Pertussis glycerol vaccine insures the equivalent of a freshly prepared vaccine at all times.

Reports indicate that the vaccine is probably from eighty-five to ninety per cent. efficient as a prophylactic; and when used in the treatment of whooping cough it diminishes the paroxysms, lessens the vomiting, shortens the duration of the disease and tends to prevent bronchopneumonia.

12. Severe serum reactions occur almost wholly after primary injections of serum. The fear of repeating a serum injection because of having sensitized the patient is practically groundless, for there need be no fear of giving a second intramuscular or subcutaneous injection to any person who has not suffered severely from the first injection.

The eye test is now recommended as the most reliable method of testing for hypersensitiveness to horse serum; but for practical purposes this test may be limited to those patients whose history of asthma or hay fever indicates that severe serum reactions will develop. With such a history and evidences of hypersensitiveness as revealed by the eye test, fractional administration of serum in doses of 0.1 c.c. subcutaneously and increased every fifteen minutes may be successful in inducing some tolerance.

Some Observations on the Bromsulphalein Test in the Clinical Study of Liver Functions.*

JULIUS FRIEDENWALD, M.D.
and W. W. ARMSTRONG, M.D.
Baltimore, Md.

Since the introduction of the newer tests for the study of liver function much interest has been manifested in the clinical application of these procedures. It was soon ascertained that unlike in a similar study of the kidney, an organ whose function is largely limited to excretion, that the liver activity is far more complicated inasmuch as this organ has numerous functions, some of which up to the present have not been fully ascertained. On this account any functional test designed to measure liver abnormality must necessarily be limited in its application and consequently the results obtained must be interpreted with caution. Further difficulties arise, too, in that in any disease of the liver all functions are not equally disturbed or involved and consequently no single test could possibly measure hepatic function as a whole for a disturbance of one form of activity does not necessarily indicate an equal disturbance of others. Furthermore inasmuch as bile cannot be collected unmixed from intestinal contents through the duodenal tube in a pure state a complete study of this secretion for diagnostic purposes is in consequence extremely difficult.

Studies on liver activities have likewise established the fact that this organ is possessed with a large factor of safety and consequently with the power of still functioning normally even though a large part be removed or be diseased.

On this account from the recent studies of Green, McVicar, Snell, Walters (1) and others the conclusion

*From the Gastroenterological Clinic of the Department of Medicine, University of Maryland, Baltimore.

has been reached that one cannot rely upon a single test alone, but that the combined study of several positive tests is of great value as indicating the probable presence of definite hepatic disturbance. According to these publications, the finding of positive serum bilirubin together with phenoltetrachlorphthalein tests is of especial diagnostic value in the study of patients with hepatic involvement.

Many observations have appeared since Rosenthal (2) first introduced his phenoltetrachlorphthalein test attesting to its importance as a means of determining disturbances of liver function. In a publication presented by us (3) the following conclusions as to the value of this test were drawn

1. This test is a valuable means of determining liver function for, when injected intravenously, it disappears rapidly under normal conditions at a uniform rate; while on the other hand a greater or less retention is noted corresponding to the degree of liver disturbance.

2. In catarrhal jaundice marked retention is noted, a condition which continues on for a considerable period of time following the disappearance of the icterus, which strongly suggests that we are dealing in this condition with some distinct disturbance of the liver cells.

3. In cirrhosis of the liver, retention of the dye may occur to a greater or less degree. As Rosenthal and others have pointed out due to the chronicity of the disease, the liver may undergo a reserve compensatory hyperplasia in consequence of which even with a more or less extensive lesion normal or nearly normal findings may be obtained.

4. In all instances of cancer of the liver retention occurs to a rather marked degree.

5. In syphilis of the liver retention of the dye may or may not occur depending largely upon the degree of involvement.

6. In cancer of the pancreas with secondary liver involvement marked retention is ordinarily noted.

7. In chronic cholecystitis, cholelithiasis and affections in which the liver itself is not severely involved retention is never observed. This finding may be of value in the differential diagnosis between certain affections of the liver, gallbladder and extrahepatic lesions.

8. Finally from these observations it is evident that this test as simplified by Rosenthal is of considerable value as a means of determining liver function; it should be routinely performed whenever there is evidence of liver involvement since it offers much diagnostic aid.

However, attention has been called during the past year especially by Maurer and Gatewood (4) and Rosenau (5) to the danger attendant upon the use of phenoltetrachlorphthalein when employed indiscriminately in determining liver function. Following the use of this dye in some instances thromboses, local inflammatory reactions at the seat of the injection and chills have been noted by certain observers. A few deaths due to its use have also been recorded.

Maurer and Gatewood conclude "that the ideal dye for liver function must be nontoxic; it must be a crystaloid. Its primary removal from the blood stream must be solely by the liver. It must remain in the blood a sufficient length of time for determinations to be made, and its ultimate removal from the organism must be solely by the liver patenchyma cells." Recognizing the objection to the employment if phenoltetrachlorphthalein as a test of the liver function as noted by Maurer and Gatewood, Rosenthal and White (6) have recently also called attention to a few of its disadvantages. For example, the amount of the dye necessary for a test is quite large. Five mg. per kilogram of body weight and the concentrations that it reaches in the blood never exceed thirty-five per cent. of the amount injected even in severe liver disease.

In order to overcome these difficulties, Rosenthal and White have introduced a new dye bromsulphalein (phenoltetrabromphthalein sodium sulphonate) which they consider ideal for the purpose of determining liver function.

The greater concentrations reached by the dye in the blood make it possible to employ a small dose.

The dye can be utilized according to these observers intravenously in doses of two mg. per kilogram of body weight and is nonirritating to the vein wall. It may be injected in concentrated solution without further dilution with normal salt solution.

The method of employing this test as advised by Rosenthal and White (6) is as follows:

The patient is weighed and the dosage calculated on a basis of two mg. per kilogram of body weight. The body weight of the patient in pounds divided by fifty-five will give the exact quantity in c. c. of the five per cent. solution required. It may be measured by drawing it into a sterile five c. c. syringe and then slowly injected directly into an arm vein; the injection should be sufficiently slow to occupy one minute, and care should be taken not to allow infiltration of the dye outside the vein. Thirty minutes after injection, a sample of blood (four or five c. c.) is drawn, preferably from the opposite arm, by allowing the blood to run through a needle directly into a dry test tube. In cases of early liver disease it may be advisable to obtain also a sample of blood at exactly five minutes after injection.

After the blood has coagulated it is centrifugalized, and the clear serum is pipetted into two small test tubes. To one of these is added one or two drops of a ten per cent. solution of sodium hydroxid to bring out the color of the dye, and to the other tube a drop of five per cent. hydrochloric acid to clear the serum of any hemolysis. The amount of dye present is now estimated by direct comparison with a series of standards. The tube of clear, acidified serum is placed in front of the standard in a suitable comparator box, and by simultaneously looking through both tubes a comparison can be made with the colored alkalized serum.* "

According to Rosenthal and White, under normal conditions five minutes after the injection twenty to fifty per cent. of the dye is present in the serum with an average of thirty-five per cent. and in thirty minutes the serum is free of the dye.

Following the method advised by Rosenthal and White our observations extend over a series of fifty-two patients affected with various types of digestive disturbances. Of these there were two cases of

*Permanent standards with comparator box as well as bromsulphalein in sterile ampules containing a five per cent. solution may be obtained from Messrs. Hynson, Westcott and Dunning of Baltimore.

catarrhal jaundice; five cases of cirrhosis of the liver; nine cases of cancer of the liver; one case of syphilis of the liver; five cases of cancer of the stomach; two cases of cancer of the pancreas with jaundice; eleven cases of chronic cholecystitis; seventeen cases of gastric disturbances in the form of achylia gastrica (7); and hyperchlorhydria (10).

The method employed in these cases was identical with that described by Rosenthal and White; two mg. of bromsulphalein per kilogram of body weight were injected intravenously and the blood withdrawn in five minutes and thirty minutes following the injections and the determination of the percentage of the dye remaining in the plasma estimated.

In no instances were there any indications of local inflammatory reactions, thromboses or toxic signs in the form of chills and fever.

CATARRHAL JAUNDICE

In the two cases of catarrhal jaundice studied by us, the results were similar to those obtained by Rosenthal. A considerable retention was noted in both instances, jaundice being marked. As was noted in our former publication, in this affection there is present a definite disturbance of the liver cells to such a degree that a considerable time must elapse following the disappearance of the jaundice before normal liver function is again restored.

2	K. T.	29	M	62	36

CIRRHOSIS OF THE LIVER

In our series there were five cases of portal cirrhosis. In all there was a certain amount of free dominal fluid present. In three of the cases the retention of the dye was marked in two there was no retention. As has already been pointed out due to the chronicity of the disease, the liver may undergo a reserve compensatory hyperplasia in consequence of which even with a more or less extensive lesion normal or nearly normal findings may be obtained. This fact will explain the slight degree of retention noted in this disease at times.

1	R. F.	42	M	30	0

CANCER OF THE STOMACH

In the five cases of cancer of the stomach normal values were obtained in every instance. Attention must again be called to these findings as of especial interest in as much as they point to this test as a possible means of differentiating between carcinoma of the stomach when this organ is alone affected or when at the same time the liver is likewise involved.

GASTRIC DISTURBANCES OF A BENIGN TYPE

There were seventeen cases in this group; of which seven were cases of achylia gastrica and ten of hyperchlorhydria. In all the Rosenthal-White test revealed normal findings.

CONCLUSIONS

Due to certain inherent qualities of the liver itself it is now generally admitted that it is not possible to rely upon a single test alone in determining the variations in liver function, but that a combined study of several is necessary to arrive at a definite conclusion.

The Rosenthal "tetrachlor" test still continues to hold a valuable place when combined with other functional tests in determining liver function. However, due to its toxicity as noted in some instances produced by the large dosage of the dye as well as to the local reaction at the seat of injection in others, caution must be exercised in its application.

On the other hand, according to our observations, quite as reliable results may be obtained with a far less toxic dye; bromsulphalein as advised by Rosenthal and White. This dye is utilized in much smaller quantities and when administered in the proper dosage is free, according to our experience, from harmful effects. On this account the conclusion has been arrived at by us that this dye should be utilized from now on in all instances in place of phenoltetrachlorphthalein as an aid in determining hepatic function.

The Serology of General Paresis in the Malaria Treated Cases

ARMANDO FERRARO, M.D.
and THEODORE C. C. FONG, M.D.
St. Elizabeth's Hospital, Washington, D. C.

(*Concluded from page* 610)

Mentally his stream of talk was unlimited, irrelevant and incoherent. He walked aimlessly about the wards. He possessed an exaggerated ego, had flight of ideas and unnatural habits. He wanted to purchase all vacant real estate. He had numerous other plans and schemes for investment. He entertained ideas of persecution and imagined that his relatives were responsible for his incarceration. He denied all hallucinations. His memory, insight and judgment were impaired. He was oriented in all spheres.

On July 5, 1924, this patient received the malaria treatment and had eleven paroxysms. His serology prior to the treatment was as follows:

April 18, 1922—Blood W.R. 4 plus, C.S.F. W.R. 4 plus, Globulin 2 plus, Cells 28, Gold curve 5555543210.
July 19, 1922—Blood W. R. negative, C.S.F. W.R. 4 plus, Globulin 1 plus, Cells 24, Gold curve 5544332100.
October 10, 1922—Blood W.R. 4 plus, C.S.F. W.R. 4 plus, Globulin 1 plus, Cells 10, Gold curve 5432110000.
June 6, 1923—Blood W.R. 3 plus, C.S.F. W.R. 4 plus, Globulin 3 plus, Cells 23, Gold curve 5555543211.

Following the malaria treatment, the serological findings were as follows:

April 16, 1924—Blood W.R. 4 plus. C.S.F. W.R. 4 plus. Globulin 2 plus, Cells 9, Gold curve 3444321000.
September 25, 1925—Blood W.R. negative, C.S.F. W.R. 4 plus, Globulin 1 plus, Cells 4, Gold curve 5555554200.
October 6, 1925—Blood W.R. negative, C.S.F. W.R. 4 plus, Globulin 1 plus, Cells 3, Gold curve 5433321000.
January 26, 1926—Blood W. R. negative, C.S.F. W.R. 4 plus, Globulin 2 plus, Cells 5, Gold curve 5433410000.
March 9, 1926—Blood W.R. negative C.S.F. W.R. 4 plus, Globulin 1 plus, Cells 0, Gold curve 5332100000.

Physically, the patient has gained in weight.

The patient's neurological condition at present shows: Pupils slightly unequal, the right being slightly larger than the left; right is irregular and is practically immobile to light; the left reacts slightly. Reaction to convergence and accommodation is present. There are no signs of cranial nerve involvement. No tremors of facial muscles, even in forced movements. There is a very slight tremor of the extended fingers. No adiadokokinesis. Coordination tests well executed. Muscular power and tonus are normal. Deep reflexes of the upper extremities are normal. The knee jerks are slightly hyperactive. Achilles reflex rather lively on the left; sluggish right. No Babinski. The abdominal reflexes are very sluggish on the right and normal on the left. Cremasteric reflexes sluggish on both sides. There is evident swaying in the Romberg position. The gait is normal. There is no spontaneous speech defects nor is one elicited with test phrases. Elementary calculations were well performed.

Mentally the patient is at present well oriented, in very good touch with his surroundings, memory is good, and his insight and judgment can be considered as fair. He still maintains slight persecutory ideas, which, however, do not appear spontaneously but are

apparent only after some questioning. He is still slightly irritable but, on the whole, considering his age, his mental reaction cannot be considered as far from normal.

Compared with his previous condition, he is a case of paresis which has improved quite remarkably clinically while, serologically, the cerebrospinal fluid Wassermann has remained unaltered and the colloidal gold curve continues to be paretic in type.

Case illustrating the disassociation between the serological improvement following malaria treatment.

Case IV.—J. T. F. Admitted April 20, 1923. Examination on admission revealed a rather overactive, affable male of thirty-nine years. There was a history of an initial lesion at the age of twenty-three.

The positive neurological signs were irregular and sluggish pupils, slurring of the speech, tremors of the tongue, lips and hands, and increased deep reflexes.

From the mental point of view, his stream of talk was excessive, irrelevant and incoherent. He was very boisterous and profane in his remarks. Marked euphoria was present as was emotional disharmony. He harbored visual and auditory hallucinations and had delusions of a markedly grandiose nature. He was completely disoriented; memory for recent and remote events fair. His insight and judgment were very poor. On the whole, the mental examination revealed considerable deterioration.

On August 1, 1923, this patient received the malaria treatment. He had a series of ten paroxysms at irregular intervals. His serological findings prior to the inoculation were as follows:

May 4, 1923—Blood W.R. 4 plus, Cerebrospinal fluid W.R. 4 plus, Globulin 2 plus, Cells 57, Gold curve 5554321000.

Following the treatment, the findings were as follows:

November 14, 1923—Blood W.R. negative, Cerebrospinal W.R. 4 plus, Globulin 1 plus, Cells 8, Gold curve 5455421000.

April 23, 1924—Blood W. R. Acetone negative, Cholesterin 1 plus, Cerebrospinal W.R. 4 plus, Globulin negative, Cells R.B.C. Gold curve 3333210000.

August 27, 1924—Blood W.R. negative, Cerebrospinal fluid W.R. 4 plus, Globulin trace, Cells 7, Gold curve 0122100000.

January 30, 1925—Blood W.R. negative, Cerebrospinal fluid W.R. negative. Globulin trace, Cells 4, Gold curve 0001110000.

June 9, 1925—Blood W.R. negative, Cerebrospinal fluid W.R. negative, Globulin 1 plus, Cells, R.B.C. Gold curve 0123333100.

September 9, 1925—Blood W.R. negative, Cerebrospinal W.R. negative. Globulin 1 plus, Cells 4, Gold curve 0123310000.

April 4, 1926—Blood W.R. negative, Cerebrospinal fluid W.R. negative, Globulin 1 plus, Cells 6, gold curve 1111100000.

At present this patient remains in good physical condition.

Neurologically, his pupils are unequal, the right being slightly larger than the left; both are irregular; reaction to light is absent. The oval of the mouth is deviated slightly to the left as is the tongue. His speech defect has become more marked. There is slight Rombergism. The deep reflexes are sluggish. The abdominal reflexes are not elicited and the cremasteric reflexes are very sluggish. The Achilles reflexes are normal and there is no Babinski. Coordination tests are well performed. No adiadokokinesis. There are no tremors of the hands or the fingers.

From the mental point of view his stream of talk remains rambling, incoherent and irrelevant. Emotionally he is flattened. He continues to be delusional and the delusions remain grandiose in their trend. He denies hallucinations but they are undoubtedly present. Memory remains very poor; he is disoriented in all spheres; and his insight and judgment are totally lacking. On the whole, there has been no clinical improvement while, serologically, the reverse has been true.

* * *

All our cases, except a few, have received intravenous treatment, following malaria inoculation. The amount of the treatment has varied from case to case having been intense in some and mild in others. An important problem, from the theoretical aspect, is to establish, to what extent the malaria alone is responsible for the serological improvement or even serological recovery and to what extent the following intravenous treatment induces the above mentioned changes. In other words, how does the malaria treatment act? Does it act alone or does it make the tissue more accessible to the intravenous treatment, following. Our material still leaves the question unsolved, although we must admit, from the practical point of view, that malaria is responsible for the improvement acting either directly, or indirectly in paving the way for the intravenous treatment.

As a matter of fact, we never knew before this era, such surprising serological improvement, following thirty-six months, a negative Wassermann reaction of the cerebrospinal fluid, in sixty-eight per cent. of the cases. Although cases were known which, following intense specific treatment, showed serological improvement or even eventual recovery, we must not forget that these cases were few and that not later than 1920. Haguenau in France could still speak, as a rule, of the irreversibility of the serology of general paresis by any kind of treatment. We can then easily believe that malaria treatment must have played, in some way, an important rôle in determining the astonishing results on the serology.

It is desirable that the serology of cases, treated exclusively by malaria, should be reported in order to compare the results with our own. The theoretical question of the method of action of the malaria treatment might then be solved. The very few cases that we have in which no further treatment followed the malaria inoculation, do not permit us to make as extensive a comparison although some of them actually show negative serology.

CONCLUSIONS

1. The treatment by malaria of general paresis exerts a surprisingly beneficial influence upon the serology.

2. The serological improvement gradually increases from fifteen per cent. of the cases within six months from the date of malaria inoculation to eighty-five per cent. of the cases within thirty-six months.

3. The first element which improves following the malaria treatment is the pleocytosis, which is reduced within a few days following the treatment. Of the cases of more than twenty-four months standing, 95.7 per cent. show great improvement while fifty per cent. show a complete reversal to the normal number of cells.

4. The globulin content, although it improves grad-

ually, shows a less pronounced reduction than the cell content.

5. The Wassermann reaction of the cerebrospinal fluid is third in order of improvement. The rate of improvement, which within the first six months is twenty per cent., is increased to ninety per cent. within thirty-six months. Sixty-eight per cent. of the cases of thirty-six months standing show a complete negative reaction.

6. The colloidal gold reaction is the most resistive element to the treatment as within twelve months only twelve cases of the thirty-nine show signs of improvement. The improvement then increases gradually although the reversal to an absolute normal curve is really seldom.

7. The blood Wassermann rapidly improves and within the first six months twenty-eight per cent. of the cases already show a negative reaction. After thirty-six months the percentage reaches eighty-six.

8. Occasionally, in the earlier stages following the malaria treatment, some of the serological reactions are likely to become worse for a temporary period. It has been noticed that in a few cases, although the clinical improvement is unmodified, the serology, especially the colloidal gold reaction, is very apt to become slightly worse.

9. No parallelism was found between the serological improvement and the maximum temperature of the paroxysms while parallelism is evident between the number of chills and the percentage of improved cases.

10. In the earlier periods following the malaria treatment there is no parallelism between the clinical and the serological improvement. The parallelism is found later as within thirty-six months from the date of the treatment all the clinically improved cases show a serological improvement. Conversely, not all the serologically improved cases show a clinical improvement.

Practical Therapeutics

Physiotherapy Treatment of Ethmoiditis

CHARLES R. BROOKE, M.D.

Newark, N. J.

Physiotherapy, in recent years, has been found to give positive benefit in severe, acute and in more or less resistant chronic pathological and symptomatic conditions of the nasal accessory sinuses.

Diathermy has been found to be the modality of choice in our physical armamentarium for the treatment of ethmoiditis, acute, subacute or chronic stages. The treatment by diathermy must not be considered from any other point of view than heat production, and it should be used only when heat is therapeutically indicated. The application of heat has a distinct value in therapy and diathermy adequately produces heat which can be regulated as to dose, accurately localized in the affected tissues, and conveniently applied to any part of the body. The action of diathermy produces a definite warming of the tissues in the path of the current between the electrodes, the effect of which is an increase of arterial blood supply, increased drainage, analgesic, improved local nutrition and metabolism, thus a decided favorable influence on the disease process.

In the treatment of ethmoiditis, the radiant light and heat from a standard rediovitant applicator, preferably carrying a 1000 or 1500 watt blue bulb, must be given preference to diathermy in the acute stage. The lamp reflector is directed over the face for twenty to thirty minutes, distance tolerance to patient, the eyes are protected with small moist packs of absorbent cotton, if sensitive to light, otherwise the light and heat is applied to the exposed closed lids. When the absorbent cotton is used it should be made to fit snugly over the orbital region, leaving the bridge of the nose, supraorbital and infraorbital regions exposed as much as practical to permit direct irradiation. The application of radiant light and heat produces a definite hyperemia, relieves congestion, the sense of fullness in the head, soothes the pain, thus promoting comfort to the patient.

The application of diathermy in subacute and chronic ethmoiditis can be given in two ways, the modified sedative or the direct sedative, the former being the choice of the writer.

The application of modified diathermy is made in the following way: A dispersive inactive triangular shaped electrode is used, made of 22 gauge combination metal (fifty per cent. each of lead and tin), measuring three by four inches. This electrode is well soaped and applied to the upper cervical and occipital regions, which area should likewise be soaped; the apex fits well up to and slightly over the occipital prominence, the operator being careful to shape and mold the metal to the part to insure perfect contact. It is then bandaged firmly to the part, a semielastic bandage being preferable, to secure good coaptation; the connection is made to one of the d'Arsonval binding posts of a dependable high frequency machine, having true resonance, in the usual manner. The active electrode is a nonvacuum electrode, the size of which ranges in character, depending on the regions to be treated, and is connected to the other D'Arsonval binding post. The position of the patient may be either sitting or lying, the latter is preferable as it permits complete relaxation. At first the active electrode is moved slowly over the involved area, using a current strength which is comfortable to the patient. After warming the affected area, together with the adjacent areas of distribution of neuralgic pains, the electrode is allowed to remain directly over the ethmoid region as long as tolerable to the patient. This concentration can be made only for one half to one minute duration but must be repeated in sequence with first step of the application for twenty minutes duration.

The application of direct diathermy is the choice method in uncomplicated ethmoid sinus disease. In this application the active electrode is a strip of metal placed over the affected ethmoid region or regions of sufficient size to cover the forehead, extending to temporals and wide enough to fit over the supraorbital ridges. The inactive dispersive electrode of the same material but larger is placed over the upper cervical spines. A current strength to tolerance of the patient is allowed to pass for twenty to thirty minutes duration, the electrodes being moistened and bandaged on in the usual way, being always careful to secure firm coaptation to prevent arcing of the current.

In pansinusitis with neuralgic pains of a varying intensity, the combined application of direct diathermy and modified diathermy has given notable results. This combination treatment should be given for about thirty minutes, allowing about twenty minutes for the direct and ten minutes for the modified types of diathermy.

The application of intranasal high frequency and intranasal ultraviolet rays are invariably given following the application of radiant light and heat or diathermy to the facial regions, for relief of ethmoiditis.

The intranasal high frequency application is given with a nonvacuum insulated nasal electrode and is attached to the Oudin terminal of a high frequency machine. Before the electrode is inserted into the nasal cavity, the current strength should be tested on the operator's lip until a soothing warmth is felt; this will be about the currect dosage to be tolerated by the patient. The electrode is inserted as far back into the nasal chamber as possible, beginning at five minutes duration, increased one minute until ten minutes is reached which is the maximum dose to each nasal fossa. The intranasal high frequency currents thoroughly heat and vascularize the nasal mucous membranes increasing drainage and thus assisting restoration of normal function about the sinus openings.

The intranasal application of the ultraviolet rays is given with a nasal quartz applicator attached to a watercooled lamp. The applicator at first is inserted

gently as far back into the nasal cavity as possible, then is withdrawn slowly to permit of fractional irradiation to the entire mucosa because most of the rays are emitted at the tip. The tip of the applicator can be directed upward or downward approaching the affected sinus opening as near as possible. Duration of treatment at first lasts one minute to each nasal fossa, fractional irradiation about fifteen seconds, this is increased one half minute each subsequent treatment up to five minutes or lower depending on the symptoms of the case. The ultraviolet rays produce a definite bactericidal effect on the nasal mucosæ.

During the course of treatments outlined for the relief of ethmoiditis patients usually remain at their work in comfort. The progress in nearly all cases is uniform and ultimately beneficial. The length of time to obtain maximum improvement varies in accordance with the individual case, duration, type of infection, its severity, extent of involvement and the bodily resistance of the host.

Treatment should be given at first daily, gradually reducing to alternate days and then to more infrequent applications as symptoms require. It has been noted that when treatments are started during the onset of symptoms, prompt relief can be attained after a few applications, otherwise, treatments must usually include a prolonged course to reach maximum improvement.

CONCLUSIONS

1. Many favorable results have been achieved by the physiotherapy technic above described in ethmoid sinus disease.

2. Radiant light and heat, diathermy, modified and direct, intranasal Oudin high frequency current and intranasal ultraviolet rays are the effective modalities used.

3. The exact technic of application and the sequence of modalities employed are essential for success.

13 Pennington Street.

The Treatment of Hepatic Venous Cirrhosis

CHARLES GREENE CUMSTON, M.D.
Geneva, Switzerland

(*Concluded from page* 620)

It is for the same reasons and frequently because the hepatic cell is seriously involved in venous cirrhosis that surgical treatment has been disappointing, namely omentopexy. In actual practice, the peritoneum in venous cirrhosis is pathologically changed so that its absorptive power is decidedly impaired, hence the operation does not relieve the portal hypertension nor the insufficiency of the collateral cavo-portal circulation, and I regard it as both useless and not devoid of danger in these cases.

The treatment of venous cirrhosis has still another objective, namely, to deal with the cause of this affection. We all know that alcoholism is of first etiological importance, but it is not the only one and the part played by syphilis, combined with alcohol, appears most important at the present time. The therapeutic results go far to sustain this supposition. Specific treatment to be effective must be begun early in the process. It becomes both useless, nay dangerous, if there are marked symptoms of hepatic insufficiency and if the liver, completely sclerosed, presents degenerative lesions.

Let us first consider the old specific medications, mercury and potassium iodide, for we at least know their virtues and inconveniences.

Mercury has long been used in diseases of the liver. Bouchard gave calomel by mouth to cirrhotic patients. He ordered one centigram daily in fractional doses as a cholagogue and specific.

During the last few years the double salts of Hg. have been given by intramuscular, intravenous and subcutaneous injections. Hg. cyanide, which is a good diuretic as well as antisyphilitic, has been found effective by many competent observers, but it must be used with prudence. The first injection should not exceed one half to one quarter cubic centimetre of the solution, in order to ascertain the patient's susceptibility to the drug. The care of the teeth, it is needless to say, must be adequate. The functional activities of kidney and intestine are to be examined into and as advised by Milian, a little bismuth bicarbonate may be simultaneously given *per os* to prevent trifling diarrhea, although some looseness of the bowel is far from detrimental in portal hypertension.

The simultaneous use of hepatic extract, especially in subcutaneous injections, will allow one to give a series of ten injections of cyanide without any intolerance to the drug or the development of mercurial intoxication. This new notion, due to Villaret, is particularly important and in respect of the arsenic compounds it has a very great bearing, because the accidents of shock, which in ordinary circumstances are frequently due to hepatic *therapeutic insufficiency,* are to a great extent avoided in instances of true hepatic insufficiency from venous cirrhosis.

The cyanide is, according to my experience, the most effective mercurial salt at our disposal, but there are subjects who offer a particular intolerance to this drug, in which case it is clear that some other soluble salt—benzoate, biniodide or salicylarsinate, etc.—must be substituted, although their therapeutic effect is less marked, and moreover, they do not possess the diuretic property of mercury cyanide.

It is my opinion that the insoluble mercurial preparations are not to be employed in cases of venous cirrhosis even when syphilis is unquestionably manifest because accumulation of the drug is all the more to be feared on account of the doubtful functional value of the hepatic parenchyma in these subjects.

Potassium iodide alone, or in combination with mercury, may often be used with advantage.

By gradually increasing doses the patient may be made to ingest from three to four grams a day and when given in keratin coated pills of 50 centigrams each, I have been able to keep cases on doses of four to five grams in twenty-four hours for weeks, without the slightest intolerance or any of the untoward complications usually ensuing when the salt is given in a solution. I also am convinced that KI is the only one of the salts of iodide possessing any real therapeutic value.

We now come to the consideration of the newer remedies, namely, the organic arsenical salts and bismuth derivatives. The organic arsenical salts, especially the arsenobenzols, are to be rejected. In apparently healthy young syphilitics in whom the hepatic parenchyma is functionally intact, they only too frequently develop—if the real truth were known—icterus and other evidences of hepatic intoxication from the drug. Hence I assume that a liver already diseased and functionally insufficient, should not be subjected to further highly toxic influences.

On the other hand I believe that the bismuth salts are highly valuable. We know their unquestionable value in the cardiovascular syphilitic processes and personal experience has been satisfactory in the treatment of venous cirrhoses. It is hardly necessary to say that during treatment the mouth, teeth, kidneys and digestive tract are to be carefully supervised. Any of the soluble or insoluble salts may be employed, but perhaps the oxide of bismuth is, on the whole, preferable to all the others, given in intramuscular injections. During treatment with bismuth injections of hepatic extract are to be given.

The effect of bismuth on the ascites has at times been remarkable when treatment has been started early in the process. But it must be prolonged and always associated with hepatic extract injections.

Treatment of Recent Pott's Fracture.—C. M. Greenslade (*Lancet,* February 6, 1926) has achieved uniformly successful results with the following plan of treatment:

Röntgenograms should be taken as soon as possible to confirm the clinical findings. The earlier the nature of the injury is accurately diagnosed and treated the better; reduction is easy when the soft parts are not fixed by adhesions; any pressure of bone ends on the skin, bloodvessels, or nerves is relieved; the muscles have not been contracted down and shortened the limb, nor has the blood and lymph exudate become organized.

Spinal analgesia is the ideal method of rendering the manipulations painless, but any form of general anesthesia may be used when spinal analgesia is not available for any reason. The only contraindications to the use of spinal analgesia are extreme youth of the patient, certain nervous disorders, and the desire of the patient to be "put to sleep." In the case of adults, 30 minims of nepenthe by mouth twenty minutes before the operation are helpful. The solution used is five per cent. stovaine with glucose; 1 c. c. of this contains 6 cg. of stovaine, an ordinary dose; however ⅓ c. c. gives adequate relaxation for manipulations around the ankle.

About ten minutes after the injection, the manipulations are begun. The surgeon stands to the inner side of the affected limb. Where the injury is on the left side, he grasps with his left hand the inner surface leg immediately above the fracture. He takes the heel in the palm of his right hand, the fingers of this hand extending around the outer border of the foot on to the dorsum. The reduction is effected by pushing the leg downwards and outwards with the left hand, and pulling the foot upwards and inwards with the right. Occasionally traction is required, but usually the reduction is carried out by the one movement described. Should there be difficulty in overcoming the backward displacement, the patient is brought down the bed so that the foot projects beyond the end. A loop of toweling is then placed over the lower part of the leg. The heel is supported by both hands. The surgeon places his foot in the loop. By pressing downward with his foot, and at the same time lifting upwards with his hands, the backward displacement is corrected. The fewer the movements made to get the alignment, the less will be the damage to the soft parts.

The aftertreatment consists of removal of the bandage and daily effleurage with as little disturbance of the fragments as possible. As soon as the major part of the swelling has subsided, ambulatory treatment with a slight removable plaster cast or a plaster of the Delbet type is instituted.

A Powerful Remedy in Obesity.—Desider Bayor (*Wiener klinische Wochenschrift,* March 18, 1926) was induced to try the use of mercurial preparations for the reduction of obesity by the observation of the marked reducing effect of mercurial preparations in syphilitic patients. Novasurol was selected because of its excellent, markedly diuretic effect, but only in such cases as show a perfectly healthy renal system.

Before beginning the novasurol treatment, every patient must be subjected to a most careful examination, with special attention to two very important points, namely, the condition of the kidney and a possible idiosyncrasy of the body toward novasurol. The latter is contraindicated with the slightest indication of a deviation from a normal kidney function. In addition, dietotherapy and iodine treatment were given. The tolerance test consisted of an injection of 1 c. c. of novasurol solution and the observance of any general symptoms, as retention of urine. The treatment is discontinued on the occurrence of the slightest evidence of gingivitis, diarrhea, albuminuria, or general weakness, even though such a small dose of novasurol would indicate a reducing effect. In all other cases, regardless of whether the obesity be due to endocrine disturbances or over feeding, the novasurol treatment may be given.

The best results are obtained, when in addition to the novasurol injections a strict dietary régime is observed. The daily ration should amount to 1200 to 1300 calories, but if the patient is still hungry, 200 to 300 calories more may be allowed.

In the beginning, 1 c. c. of novasurol is injected intragluteally every six days. A reduction in weight of 1.5 to 2.5 kg. is observed within twenty-four hours. The additional use of pluriglandular therapy is of advantage. During the novasurol treatment, the patient should avoid the ingestion of halogen salts to avoid gastrointestinal disturbances. During prolonged treatment, the patient should be made to lose about 0.5 to 2.0 per cent. of his weight every week.

Historical Medicine

The Legacy of Greece to Galen

V. Its Survival

JONATHAN WRIGHT, M.D.
Pleasantville, N. Y.

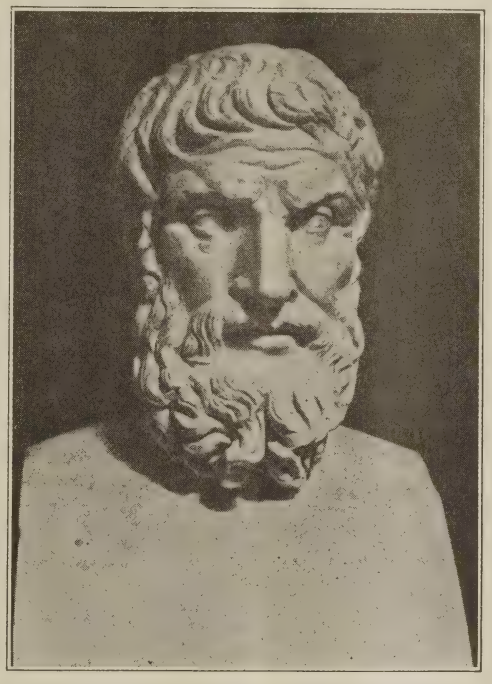
In the former pages we have found Galen frequently in dispute with Aristotle, but not infrequently acknowledging his merit and bowing to his authority. We have seen that Aristotle's dictum that Nature does nothing in vain incited him to the achievement of his greatest work, the *Utility of the Parts*. Galen was not even willing to dispense with the ancient terminology in the legacy he received. He continued to speak of Nature and the Soul when it was becoming the fashion to speak of the vegetative soul and the sensitive soul (1a). He named his famous work with that of Aristotle in mind on the *Parts of Animals*. He is not lacking in reverence for Aristotle then, but when he encounters the Stoics and Peripatetics who followed Aristotle he does little but flout them. We have seen him in acrimonious argument for page after page with Chrysippus, but on Epicurus he dwells with scarcely less censure. Epicurus was in vogue in philosophy for many centuries in the decaying glory of Greece and the rising glory of Rome. Then and long after, even up to the present time, his philosophy has been distorted into one of selfish indulgence and narrow minded views. He was born in Samos in 341 B.C. and having known poverty he taught the people of Athens how to laugh at it and the misfortune which then lay heavily upon them, but this was something Socrates had preached before him. It was a tenet of many Stoics and Sceptics and Cynics after him who followed in the wake of Zeno and Diogenes.

It was these brought from Asia or at least from its Ionic provinces the demonstration of the fallibility of the senses. Such tendencies as this in the philosophy of Athens Epicurus met with the doctrine of sense impressions—veritable dents as it were in the organs of sense by matter, I presume, impinging on them. Thus he claimed there was no escape for us from the conviction we are, after all is said, literally in touch with reality. It was thus he applied the physical theories of Leucippus and Democritus and he expanded them into the doctrine out of which Lucretius made his great poem. Like Galen with the humoral doctrines of the ancient Greek physicians he went further than Democritus and attributed apparently some sort of capability of movement to the atoms independent of what they acquired from without, but which I do not comprehend unless there is in it a trace of Aristotelianism. It is singular that a doctrine founded at least on what passed for the irrefragible truth of one civilization and inspired the literature of another should not be represented by the original words in any degree of its author, but should exist only in the fragments of it cited by other authors. We can not help thinking Pythagoras and Orpheus and Democritus and Zeno and Epicurus, though all of them did not teach by their writings, not to mention a host of others of less prominence who yet influenced the thought of their generations, must have left us a scrap of parchment or papyrus or copy of their own works if they so profoundly influenced the history of thought. We know them only in the quotations of others using them and twisting their words to their own purposes. Quite aside from the latter motive, Heiberg, whose recent work I shall have occasion to mention here shortly, shows us how apt these citations were to be incorrect and badly rendered.

Why is this? It is true the Epicureans made no great discoveries for Greek philosophy. Neither did Cicero nor Seneca nor Pliny contribute any thought to it at Rome. We have practically all these men wrote, a great part of it in each case, at least. Epicurus and Chrysippus it is true seem to have made little or no addition to the thoughts of the world before them. They too wrote enormously, but it all perished. Hippocrates lives for us in his own words, but of Empedocles, a very great thinker and a great poet, we have only sorry fragments; of Democritus scarcely more than a tradition and hardly that of Leucippus. Epicurus, whatever originality he lacked, was a great thinker and he made a wider appeal to more men probably than any who preceded him, not excepting perhaps the greatest of them. In the Graeco-Roman world why did his works perish and theirs live? He did not lack disciples as long as it lasted. Many knew his sayings by heart. One may well pause before taking refuge in the usual suggestion, weighty though it is. Plato and Aristotle appealed to man forever and the whole man, intellectually, morally and psychically, Epicurus only to man for a time and to a part of man. The former were nearer the heart of man's nature and they more often made an appeal to those able and desirous of preserving the tokens of what seemed to them wisdom. There can hardly be question of that, but there can hardly be any question that the *Morals* of Seneca are twaddle and they lived. Probably Chrysippus was worse. Seneca still lives in his commonplaces and Chrysippus perished in his own. They were both intolerable bores, but the words of one only lived. We can but conclude that Chance plays a very large part indeed in this survival of the fit and the unfit.

The wonder is any survival at all. Professor Heiberg (2) has paused long enough from his other classical studies to remind us of this. The Assyrian tiles and the Egyptian wall surfaces have preserved for us literatures, which simply as literature to the common reader seem hardly worth preserving, though Breasted has made an astonishing use of it in his own writings which may well claim a place in literature. The wax tablet of the Greek was as negligible as the school boy's slate. The papyrus manuscripts not only through the Egyptian but through the Greek and Roman eras have a few of

them come down to us in shreds from ages as remote as the hieroglyphs on the walls of Karnak. Their frailty is such they crumble at a touch even in the dry lands of the Nile, more of them agents' accounts than verses of Homer. Pasted on the lids inside of coffins and chests, untouched, they have revealed to us much history, but only a mere spark of the literature that once filled Greece and Rome with its effulgence. Egyptologists seem to have found literary merit in the writings of the Middle Period of early Egyptian history, the *Story of Sinuhe,* the *Eloquent Peasant,* the *Shipwrecked Sailor* and other compositions even of a later epoch, but like the *Poem of Gilgamesh* they require wits sharpened by the sands of the desert and understanding as ponderous as the pyramids to extract literary value from them. Yet the Battle of Kadesh and the fight Rameses II put up there, as Breasted tells it in the recent Vol. II of the Cambridge Ancient History, stirs the blood as though a blast from Homer's trumpet under the walls of Troy. These I think we may for the present leave aside, but the papyrus from the Nile was surely a slender reed on which to hang the story of the glory of Greece. What a breath in a foreign land may puff away is not a sure material to preserve the treasures of thought of a hundred generations. Parchment in the cloisters and the monasteries, sleeping there some of it long after the religion in them was dead has preserved the most of it, which I will not stop to summarize in Heiberg's tale, but the wonder grows as we read his dissertation that we have anything even of those once able to quote at second hand from Epicurus and Zeno.



Term of Epikuros (Rome, Vatican) (*after Hekler*)

Asclepiades we learn enough of from the reproaches of Galen but very little more has been preserved for us. He excited Galen's spleen even more than Chrysippus, but what he holds up for our ridicule in the whirligig of time often appeals to us as far more near what we think we now know than is to be found in the discourse of Galen. It is on Epicurus and Asclepiades he falls with particular fury. With the latter he is indignant for saying (1b) that purgation is purgation. It is of no consequence whether you get rid of offending matter in the bowel with a cholagogue or a hydragogue, so that you get rid of it.

"Asclepiades is crazy when he tries to induce us not to believe our senses" or to profit by our experience. Give a cholagogue to a person whose bowels are loaded with phlegm and the resulting evacuation harms rather than benefits the man, but after the reader of Galen gets this and much more about the rascalities of Asclepiades he sighs to think the latter after falling from a ladder and breaking his neck when a hundred did not leave something of his own for us pasted on the inside his coffin lid. Galen meets the shade of Asclepiades, dead for another hundred years or more, in the medical arena and quarrels with him on many a subject. He more often than not upbraids Epicurus too for his philosophy, but he quotes him to the disadvantage of Asclepiades on scientific grounds here. Epicurus admits that at least iron is attracted by the magnet, straw is drawn to the amber. The atoms of iron and of the lodestone, he says, go out to meet one another, become mingled together and adhere to one another. Epicurus at least agrees there is such a thing as attraction and by virtue of it food is assimilated and distributed and the excrements are voided by the action of purgatives. Just as similar qualities of the lodestone atoms and of the iron atoms attract one another, so a cholagogue draws the bile and a hydragogue carries the water out of the bowel with it. In this connection we may take note how although having this "attraction" bee in his bonnet, a theory always handy, he nevertheless does not run into the error of earlier physiologists, Praxagoras and Philotimus, who believed just as the expansion of the thoracic walls sucks air into the lungs the vessels suck blood into themselves when they dilate. Very likely then this "attraction" of Galen was not the "void" which nature abhors. It was by demonstration (1c) and by experiment on the blood vessels he refuted these predecessors, but we may well imagine that the ancient Greek in this respect went astray having the Magnesian lodestone marvel in his mind.

While this experimental work kept Galen from this kind of error in his legacy he nevertheless was influenced by the lodestone phenomenon as to the intestinal action of drugs. He says Asclepiades rejects this suggestion and we greet him as a hard headed old sinner, but yet the latter accepts the principles of Epicurus, who gave foolish reasons to explain, as above, the action of the magnet. Epicurus was not the originator of this train of thought. We find it plainly in the fragments of Empedocles how thus the tree roots draw nutriment from the ground, the stomach walls from the food. For Empedocles too in vision the light particles from the eye go out to meet the particles from the object. Thus buried is truth, a kernel among the husks of error, but neither the husk nor the kernel originated with Epicurus. Galen's criticism of this is that the little lodestone would run out of atoms after a while and there would be nothing left of it.

Epicurus wrote many books (1d) about the nature of matter—as to whether it was single or multiple, agreeing with Democritus. Both of them elsewhere Galen attempts to refute (1e) when they deny change

in the atoms, they ascribing the phenomena of change to the nature and size of them. From this, Galen says, Asclepiades finds support for his doctrine that drugs on administration are not essentially changed either. Galen says that both Empedocles and Hippocrates held to the opinion there was no mutation of the elements, but all change in phenomena was due to their combinations and separations. (1f) It is difficult indeed to follow the shades of differentiation in Galen's accounts of the ancient doctrines, for he is neither always explicit nor always consistent and sometimes contradictory when he deals with the constitution of matter, but they are easily seen to enter into his own cogitations and sometimes thus confusedly.

He rests his teleology not only on the aphorism of Aristotle declaring nature never works in a futile manner but on the passage in the second book of the *De Anima.* An eye remains an optical organ whether it is built like that of a crab or not. Walking can go on with the leg of an elephant, of a goat or of a man. Whereupon Galen, despite his adherence to the doctrine, makes a treacherous stroke at the hand which raised him for its lack of skill in dissection and the mind that taught him for its lack of perception in observation. "If this is so, dearest Aristotle, do not by the form of the body as in many of thy awkward attempts, do not judge by the form of the nerve or the tendon, but by its use." (1g) You may reject the phraseology of these old writers so as to eliminate the interposition of God or entelechy or Nature's demands, but to lose sight of the end in view, however far off, of structure is usually to lose your bearings altogether. To make it the rudder by which you steer is quite another thing and, despite his inconsistency, Galen far more than Aristotle exhibits the strange ports arrived at by such preponderating pilotage. Chemistry and the microscope often allow us now—or rather the infinite specialization at which we have arrived in science often places the end in view at such a distance we can sometimes dispense with the help of physiology or etiology either, but by no means always in our objectivity even now. The "method" of science is a joke and the "decalogue of science" is a subject for jeers. There is no method which will not often betray us into false paths. There is no method to save a fool from his folly and there is no law so pernicious as one which can not be broken. All advance is made by kicking over the barriers.

Aristotle was conscious of this. Teleology was only one path to the truth even for him, teleology no more than etiology. He declares (3) that causation practically is simply a matter of enlightenment—how far one sees the lengthening file and the converging ranks of causation behind the phenomena he means and he might have added no two persons see them exactly alike. As Robin paraphrases (4) it, it is a matter of the point of view we take of things in general. Medical etiology is usually so smug as to induce nausea. That is the feeling we get so often in reading Galen and so seldom in Hippocrates and Plato and Aristotle. Plato placed his triangles in great prominence in the mechanism of his sense of taste, but we do not find him straining his eyes out with trying to adapt them to the mechanism of the other senses. Aristotle's conjecture that sound exists where there are no ears to hear it does not travel with his general voyaging, but there is no moaning at the bar when he leaves it behind. Galen is like a porcupine. You can approach him at no angle that you are not met by the prickers of his humoral theories and like the fabulous beast he is ever darting them at the enemy, often with no more consistency than we have just seen him adjuring Aristotle, who taught him teleology. Aristotle did not well understand that hearing was an air limited sense, though he knew of Alcmaeon's theory of air waves beating on the caverns of the ear, but that did not prevent him from a weird prophetic doctrine of sense in general which has fallen true under evolutionary research. It was Aristotle taught us touch was the fundamental sense and out of that long ago seerlike pointing of the finger we came to the conception of the irritability of protoplasm. Helen Keller can hear with her fingers and the tactual interpretation of speech is an accomplishment which can be taught in the class room (5). Neither can we find cause to quarrel with Aristotle for saying it is only matter in motion which is revealed to the senses. The Unmoved Mover is hidden from them. We see in Aristotle that causation *is* a matter of enlightenment and that Galen is myopic in the matter of medical etiology. Yet as we have seen in his commentaries on the elements and in his endeavor to benefit by the legacy of the greater men before him he had a historical sense to which the science of yesterday if not altogether that of today is blind.

Finally, though I have already occupied considerable space in this essay in wondering why we have any legacy at all left us from Greece in the way of letters and philosophy and medical science, I wish to occupy a little more. We are puzzled to conjecture why the writings of genius ever perish and the writings of mediocrity ever survive. Eckermann was Goethe's Boswell without Boswell's talent and he became the butt of the wit of literary Germany. Heine says he met a man coming weeping along the road out of Weimar in 1832. Asked the cause of his sorrow, the man sobbed: "Goethe is dead and Eckermann still alive." That is the way we feel sometimes about the classics. Galen has his place in the temple of fame as unquestionably as Goethe, but when we seek him in the Hall of Fame of his day we don't find him and we are already smiling broadly at some of the premature figures in that of our own. Our wonder, if not our smiles, is excited that such a vast collection of the writings of any one man of medicine should have survived whose contemporary fellowmen did not regard him of sufficient importance even to mention. Asclepiades lives in the pages of Cicero who thought him important enough to court his favor. I have alluded in the former essay to the notice of Galen by Athenaeus, who may have been a contemporary of his in the time of Marcus Aurelius. Oribasius quoted him or collected his works for Julian the Apostate two hundred years later. Paulus Aegineta, fully five hundred years after Galen died, in his collection of notes from the ancient writers, mentions Oribasius, and Galen with less emphasis and as though he too might have been a collector of the works of others rather than an author who wrote chiefly his own.

Without Galen we would have known little indeed of Greek medicine outside of Hippocrates and very

little of Greek philosophy outside of Plato and Aristotle. Galen says he was physician to Marcus Aurelius and Commodus and the great about their courts —that he was widely known to distinguished men everywhere throughout the empire and was in frequent correspondence with many of them—he intimates his fellow practitioners thought so much of him they were constantly entreating him to lecture to them and write books for them—that he was so famous in his lifetime books were given his name, which he never wrote, in order to sell them. Others rubbed out his name and put their own at the head of books he did write, so prized was his science. In modern times he would have been in all the Sunday papers. He traveled widely everywhere in the Mediterranean lands—and not a word of his time have we about that famous man, which has come down to us unquestioned. It is "time which antiquates antiquities. . . . In vain we hope to be known by open and visible conservatories."

Rudyard Kipling on the History of Bacteriology

LOUIS J. BRAGMAN, M.D.
Syracuse, N. Y.

In *McCall's Magazine* for September, 1926, there is a story by Rudyard Kipling called *The Eye of Allah,* which deals in a romantic style with the beginnings of bacteriology and the microscope in the medieval age, and which reveals the inevitable conflict between science or light on the one hand, and the Church or darkness on the other.

John of Burgos, an artist employed as an illustrator of manuscripts in a monastery, had procured a microscope in his travels in the East. Primitive in its construction, it is described as follows:

"A stamped leather box, some six or eight inches long, wherein, bedded on faded silk, lay what looked like silver bound compasses of old boxwood, with a screw at the head which opened and closed the legs to minute fractions. The legs terminated, not in points, but spoonshapedly, one spatula pierced with a metal lined hole less than a quarter of an inch across, the other with a half inch hole. Into this latter John, after carefully wiping it with a silk rag, slipped a metal cylinder that carried a glass or crystal, it seemed, at each end."

Brother Thomas, the Infirmarian of the monastery, had for many years been speculating on medicine, especially on the cause of disease. While discussing a type of spotted fever which was prevalent at the time in England and Italy, he declared:

"I confess myself at a loss for the cause of the fever unless—as Varro saith in his *De Re Rustica*—certain small animals, which the eye cannot follow enter the body by nose and mouth, and set up grave diseases."

The artist, in the course of his observations through the microscope, had seen patterns of moving objects that appealed to him as suitable models for his drawings of devils. Accordingly he produced the following: "Some devils were mere lumps, with lobes and protuberances—a hint of a fiend's face peering through the jellylike walls. And there was a family of impatient, globular devilings who had burst open the belly of the smirking parent, and were revolving desperately toward their prey. Others patterned themselves into rods, chains and ladders, single or conjoined, round the throat and jaws of a devil that had made good his refuge. And there were granulated and conglomerate devils, mixed up with the foam and slaver where the attack was fiercest. The border to the picture was a diaper of irregular but balanced compartments or cellules, where sat, swam or weltered, devils in blank, so to say—things as yet uninspired by Evil—indifferent, but lawlessly outside imagination. Their shapes resembled, again, ladders, chains, scourges, diamonds, or globes."

The progressively minded Infirmarian had shrewdly recognized that these strange shapes, seen through the magnifying lenses, were possibly the hidden causes of diseases, and expressed himself to that effect: "As in the water, so in the blood must they rage and war with each other!"

An Oxford Friar, who was visiting the monastery, none other than Roger Bacon, the famous philosopher, was similarly impressed, and characteristically wished to verify these contentions by experimentation. But the Abbot, Stephen de Sautre, despite the fact that he was a man of science, a doctor of medicine, and "physicus before he's sacerdos," was sceptical about the advisability of keeping the instrument, stating thus his reasons:

"It would seem my choice lies between two sins, to deny the world a light which is under our hand, or to enlighten the world before her time. What you have seen, I saw long since among the physicians at Cairo. And *I* know what doctrine they drew from it. . . . But this birth is untimely. It will be the mother of more death, more torture, more division and a greater darkness in this dark age."

So despite the pleadings of Roger Bacon and Thomas the Infirmarian, the Abbot pitilessly destroyed the microscope, fearful of the wrath of the Church. And thus, by curbing a development of a knowledge of bacteriology and microscopy, and by stifling an understanding of the germ theory of disease, can the progress of medicine be considered to have been retarded by at least several centuries, according to this stimulating tale of Rudyard Kipling.

Editorial Articles

THE NEW YORK ACADEMY OF MEDICINE

At last the New York Academy of Medicine is suitably housed in a building the beauty, dignity, size and convenience of which are commensurate with its importance, and the needs and value of the institution. The history of the Academy, presented elsewhere in this issue, is one of which not only the medical profession of New York, but every citizen may well be proud.

Ever since its foundation in 1846, for the initial meeting leading to its organization was held on December 12, 1846, though formal organization was not effected until the following January, the New York Academy of Medicine has been a powerful agent for good in the life, health and welfare of the community. Not only has it brought together for consultation, for mutual instruction, and for guidance the members of the medical profession, but it has always played a most beneficent and helpful rôle in the affairs of the city. The eloquent tribute paid to the Academy during the celebration of the completion of the new building by the chief magistrate of New York was well deserved.

The organization of our first municipal board of health was due to the efforts of the Academy of Medicine. There are many other directions in which it has contributed to the public welfare.

The list of its early presidents and orators, which appears in the paper by Dr. Linsley Williams on another page, reads like an honor roll of the medical sciences. The men who made the Academy of Medicine what it is today have been great leaders of thought and of men. It would be an invidious distinction to name any one individual from among the fellows and officers of the Academy who have rendered signal service to the profession and to the community. But no one at all conversant with the history of the progress and development of the medical sciences can peruse that list without meeting many fair names and famous which have been inscribed in high places in the hall of scientific fame.

The New York Academy of Medicine offers freely to all practitioners and students, whether Fellows or not, frequent opportunities to hear and to see the leaders in every special field. Here the general practitioner, the orthopedist, the laryngologist, the gynecologist, the urologist, the psychiatrist, in fact the specialist in every field is offered an opportunity to forgather with coworkers in his own field for discussing their own special problems, and to hear the latest word from the leaders in that field.

At one of these meetings, now many years ago, Dr. George W. Crile spoke eloquently and convincingly of anociassociation. He showed on the screen the disastrous physical effects of noise on the brain cells. Since that time the barbarous clangor of bells, and the hooting of whistles as signals have been banished from the hospitals, to the great benefit of many thousands of grateful patients. And this was at but one of the thousands of meetings which have been held within the walls of the Academy. The physician who avails himself of the opportunities so freely offered by the meetings of the Academy and of its several sections, will be afforded invaluable opportunities for contact not only with the local leaders but with the great medical teachers from every section of the world.

To the serious student the library of the Academy affords invaluable assistance. More than a thousand medical periodicals in all the modern languages are on the open shelves for free consultation by all whether Fellows or not. A large and elegantly appointed reading room contains the bound volumes of all the leading medical periodicals for the past twenty years so arranged that the reader has free and unrestricted access to them.

And as the institution grows its activities continue to widen. The Public Health Committee has come to be an institution of incalculable value, not only in this community but in cooperating with public health officials in other great cities.

The committee on medical education performs a signal and most unselfish service to all postgraduate students through its Bureau of Clinical Information where the student may see a daily bulletin of all the clinics of Greater New York and may also learn any desired details regarding the opportunities for clinical instruction in all the great European centres. To maintain all these valuable activities requires not only intelligent enthusiasm and competent leadership but also involves large expenditures. Some of the funds for these expenditures are provided by the income from invested funds bequeathed to the Academy, some comes from the annual dues of the Fellows, and this has been materially augmented by a grant of $62,500 a year from the Rockefeller Foundation.

Through the careful husbanding of its resources, a fortunate investment in a site bought but not used, and a gift of more than a million and a half dollars by the Carnegie Corporation, the erection of the new building was made possible. Facing Central Park, on a plot of ground which affords opportunity for still further enlargement, the new building has been so

designed that when, if ever, expansion becomes desirable that expansion can be provided without interfering with the present building. The new building of the New York Academy of Medicine will be a source of civic and of professional pride for all time.

SMOKING AND BLOODLETTING

Fashion, capricious always, is, perhaps, especially so in medicine and surgery. At the present time there is an active crusade being carried on in this country against the use of tobacco. Dr. J. Rosslyn Carp of Antioch College, Ohio, has conducted an inquiry into the effects of the continued use of tobacco and concludes that the habit deteriorates mental capacity. Professor H. Kionka, a German authority, stated some little time ago that there is hardly a single pathological condition which tobacco cannot cause or aggravate, while Sir Humphrey Rolleston in the *Lancet,* May 22 last, holds a middle course.

Dr. Archer and Dr. Everard in their *Panacea, or a Universal Medicine,* being a discovery of the wonderful virtues of tobacco, published in 1659, warmly defended the habit, and for long it was held by the highest authorities to be an efficacious preventive of disease. Thomas Hearne in his diary, 1720-21, writes: "January 21, I have been told that in the last great plague in London none that kept tobacconists' shops had the plague. It is certain that smoaking was looked upon as a most excellent preservative. Insomuch, that even children were obliged to smoak. And I remember that I heard formerly Tom Rogers, who was yeoman beadle, say that when he was that year, when the plague raged, a schoolboy at Eaton, all the boys of that school were obliged to smoak in the school every morning, and that he was never whipped so much in his life as he was one morning for not smoaking."

Bloodletting, at one time the common medical practice, has fallen into disuse. Paracelsus was one of the first to protest against the manifest abuse of the treatment. In the feudal ages bleeding was deemed a necessity. Most of the religious houses had a flebotomaria or bleeding house in which the inmates underwent bleedings or minutions, as they were termed, at stated periods to the strains of psalmody. An old surgical writer divided his chapter on bleeding under the following heads:—1. What is to limit bleeding?; 2. Qualities of an able phlebotomist; 3. Of the choice of instruments; 4. Of the band and bolster; 5. Of porringers; 6. Circumstances to be considered at the bleeding of a Prince.

To bleed on May day was at one time a universal custom. Steele, the writer, tells of a phlebotomist who advertised for the good of mankind to bleed at "threepence a head."

The readers of Smollett may remember in one of his novels the story of a gentleman who, falling down in his club in an apoplectic fit, was immediately made the subject of a bet by two bystanders. The odds were given and accepted, and the wager was duly made, when a suggestion was advanced by a more humane spectator that a surgeon ought to be sent for. "Stay," exclaimed the good fellow interested in the result being fatal, "if he is let blood, or interfered with in any way, the bet doesn't hold good."

About bloodletting, by the lancet, leeches, and cupping or boxing, as it was termed in the days of "good Queen Bess" and much later, the curious may obtain many interesting particulars in the works of Bulleyn, the physician of the Queen.

Venesection was carried to an extreme extent in the seventeenth and eighteenth centuries. John Capley Lettsom, the founder of the Medical Society of London and one of the first physicians of the time, was notorious for his frequent use of the lancet. He said of himself or a lampooner of that age of lampooners said of him:

> When patients sick to me apply,
> I physics, bleeds, and sweats 'em;
> Then—if they choose to die
> What's that to me—I lets 'em.

There is little doubt that in some cases a judicious bloodletting did good, but it became so much the vogue that it was abused without limit, and the reaction against it was so strong that as a medical or surgical procedure it was abolished entirely.

MIND AND MATTER

In the second Halley Stewart Trust Lectures, delivered on October 14, 1926, Sir Oliver Lodge presented a clear survey of the entire field of modern mechanical developments resulting from scientific discovery, and of the influence of new powers of locomotion, communication and control of disease upon progress in general. He maintained that all things considered that influence is excellent; but that all advancement towards the attainment of the welfare of mankind must depend upon the degree in which goodwill prevails, and in which men are inspired by the desire to fulfil that purpose.

Briefly, science teaches the same elementary truth as that which the great religions have consistently advocated. Sir Oliver expounded the nature of the material universe, and its relation to the universe of mind. It is commonly affirmed, as a provisional theory, that the material universe is infinite in space and in time. The human intelligence is capable of conceiving the idea of infinity although not understanding how infinity is possible. The lecturer showed that it is possible that a definite form should possess the quality of infinity. Upon the surface of a sphere there are no beginning and no end, and therefore the possibilities of movement are in a sense

infinite. An alternative hypothesis may be offered, which is that the universe is a purely subjective phenomenon, interpreted by means of the limited perception of the senses, so that if the means of perception were changed the universe would appear entirely different. If that theory were pushed to its logical conclusion it would be necessary to regard the visible universe as in the nature of an hallucination.

As to whether mind produces, or is produced by, matter, it is Sir Oliver Lodge's opinion that for the time being the apparent duality must remain an insoluble problem; but he regards every new discovery concerning the nature of matter as tending to do away with the distinction between mind and matter and to blend the two into that unity which the mind instinctively demands. There is nothing in the material universe but two electric charges, which incessantly revolve about the ninety-two atoms and the various groupings of those atoms. So far as one knows at present, these are the units of which the entire universe is composed. At some stage in its evolution, to inorganic matter is added the mysterious force called life, and in every manifestation of the universe, from the least to the greatest, the same immutable purpose, the same infallible care, are evident. Nature is lavish but never wasteful and Sir Oliver justly urged that the knowledge of these things must be helpful in the uncertainty of man's brief existence.

MUSIC AS A THERAPEUTIC AGENT

There are many ways of gaining health or of improving one's health. In fact, at the present time, the various aids to health advocated in this direction are so many as to be almost embarrassing. For particular complaints and conditions, massage, electricity, x rays, radiant light, psychotherapy are recommended and the already overworked physician, as a rule, has not the time to learn how to apply such methods correctly.

Long ago music was vaunted for its beneficial properties in certain states of ill health. In history there is frequent mention of the healing powers of music especially in some phases of illbalanced mind.

Theophrastus and Democritus refer to valuable therapeutic properties of music, and in the Roman and in medieval Italian writings music is spoken of favorably, often as curative particularly for the relief of pain and for collapse after serpent bites. In more modern times, the uses of music and medicine have been discussed freely and at length and in a work brought out by Dr. Agnes Saville a chapter was devoted to the consideration of the remedial and curative properties of music.

The New Health Society *Bulletin,* in a recent issue, comments on the matter and it is pointed out that under modern and scientific methods of examination it is probable that many of the cases described as having been healed by music would be classed as belonging to the group of hysterical and other functional disorders, which readily respond to many methods of suggestion. However, even if this be the explanation, it does not detract from the value of the therapeutic agent, while pleasing music possesses decided advantages over some of the psychotherapeutic measures employed.

REPORT OF NEW YORK'S CHIEF MEDICAL EXAMINER

The total number of deaths in New York City during the year 1925 were 71,864. Of this number, 13,353 cases were handled by the office of the Chief Medical Examiner of New York City, according to a recently issued report of that official. This was an increase over the previous year of 765. The report covers vehicular accidents, homicides and suicides, asphyxiation by gas, and "natural" deaths, including sudden demise and those unattended by a physician or occurring under suspicious or unusual circumstances. These natural deaths numbered 6,692; the violent deaths 5,581.

Highway accidents were responsible in 1925 for 1,272. Of these, 589 were caused by pleasure cars, and 343 by commercial automobiles. The children and young people who lost their lives in this, numbered 462. Of these the largest number, 238, were between the ages of five and ten; ninety-seven were under five; eighty-two were between ten and fifteen; and forty-five between fifteen and twenty.

The next largest number of deaths came from suicides and amounted to 994. Illuminant gas was used by 388 of these, 145 hanged themselves, and 134 jumped from high places.

Alcoholism claimed the largest number of victims among general diseases, namely, 585. There were 356 homicides, of which 248 were caused by shooting and fifty-seven by stabbing. There were twelve cases of infanticide. Pulmonary tuberculosis caused 290 deaths; carcinoma, 123; elevator accidents eighty-seven, of which forty-seven were caused by falls into shafts, thirty-six persons were crushed by elevators, three were killed by the elevator's falling, and one fell into a dumbwaiter shaft; eighty-two deaths were caused by sepsis, forty-nine from diabetes, forty from tetanus, and twenty from diphtheria. It must of course be borne in mind when considering these statistics that they pertain only to cases handled in the Office of the Chief Medical Examiner of New York City.

Among miscellaneous casualties were eight deaths from diving, six from baseball, six from coasting, three from fist fights, and one from football.

The Heart in Thyroid Disease

ERNST P. BOAS, M.D.

New York

Much has been written concerning the goitre heart, but a survey of the literature and of the text books reveals little uniformity of opinion and few clear concepts of the underlying pathological physiology. The goitre heart is found in simple, as well as in exophthalmic goitre, but the nature of the cardiac disturbance in the two conditions is quite different.

With simple goitre cardiac hypertrophy is usually constant and proportional to the size of the goitre. Marine (1) has demonstrated this in animals and believes that the cardiac enlargement is a work hypertrophy due to tremendously increased vascularity of the thyroid in the earlier stages of the goitre. The dilatation of the thyroid arteries and veins, which may include the larger branches connecting them with the aorta and superior vena cava, short circuit a large part of the blood flow, so that the heart must handle a larger volume of blood with each systole. The cardiac hypertrophy, therefore, is analogous to that described in certain arteriovenous aneurysms. Others, among them Rose (2), Minnich (3), and Blauel (4), have attributed the cardiac enlargement to an increased blood pressure in the pulmonary circulation brought on by the obstruction to respiration consequent upon compression of the trachea by a large nodular goitre, which is often followed by recurrent attacks of bronchitis, emphysema, and occasionally by bronchiectasis. In support of this theory, it has been pointed out that in these cases the right ventricle in particular shows hypertrophy and dilatation. Be that as it may, this can obtain only in a limited number of cases. Still others, following Kraus (5), believe that toxic influences are the determining factors. In many cases both toxic and mechanical moments seem to play a rôle.

There may be few symptoms referable to the heart in the mechanical form of goitre heart. Dyspnea due to tracheal compression, emphysema, and recurring attacks of bronchitis usually dominate the clinical picture. In time myocardial insufficiency and dilatation of the right heart, manifested by palpitation, dyspnea, congestion of the lungs and edema, set in. The patients with the socalled toxic goitre heart complain of palpitation and precordial pain. They may show tachycardia, slight tremor, sweating and dermographia. The heart is hypertrophied. Many patients with simple goitre exhibit combination forms of the mechanical and toxic goitre heart.

Whatever the etiological factor, the heart associated with long standing simple goitre in time may become insufficient, and signs of cardiac failure then dominate the clinical picture and eventually may lead to death.

The röntgen picture of the heart, associated with simple goitre, shows, as has been pointed out by Bauer and Helm (6), a prominence and exaggerated pulsation of the region of the pulmonary artery, with a narrow, high placed aorta. The transverse diameter of the heart is not much enlarged. They interpret this picture as an indication of a constitutionally hypoplastic heart.

TREATMENT

The cardiac disturbance associated with simple goitre is very resistant to ordinary cardiac therapy. Digitalis is usually without effect. When the socalled toxic symptoms predominate, relief may be expected from operative removal of the goitre. Indeed, the heart may recede in size after operation.

The heart in Graves's disease presents quite a different picture. Pathologically, one finds frequently moderate hypertrophy and dilatation of both ventricles, with fatty infiltration of the heart muscle cells (7). The anatomical changes in the heart muscle, however, rarely parallel the severity of the symptoms. In some cases small scars with interstitial or perivascular round cell infiltration are found scattered through the heart muscle. Similar lesions may be found in the hearts of patients with simple goitre (8). Several observers have experimentally produced similar lesions by feeding desiccated thyroid to animals (9, 10). Recently Goodpasture (10) has described two cases of Graves's disease with extensive myocardial necrosis, unaccompanied by inflammatory reaction or by coronary artery disease. He points out, however, that this is an uncommon finding. The cause of the cardiac disturbance remains obscure, although it is generally believed to depend on a toxemia. It has been suggested that pressure on the cardiac plexuses by a substernal

goitre may be responsible in some instances. Chiari (11) has pointed out that cardiovascular anomalies, such as the dropped heart and narrow fragile arteries, as well as vasomotor instability, frequently determine the intensity of the cardiac symptoms in Graves's disease. He recalls that functional heart symptoms may precede the onset of Graves's disease and may continue after the disease has become arrested.

The increased basal metabolism so constantly observed in Graves's disease and particularly the close correlation between pulse rate and basal metabolism (12) point to another factor which must affect the heart. With the heightened metabolism there is a greater consumption of oxygen by the tissues and an increased elimination of carbon dioxide. Since there is no change in the hemoglobin and red cell content of the blood nor in the oxygen saturation this necessitates an increased minute volume flow of blood through the tissues. This may be attained by an increased systolic output of the ventricles or by an accelerated heart rate or by both. These factors, acting continuously for twenty-four hours of the day for months at a time, must place a great strain on the heart and result in cardiac hypertrophy and dilatation, and probably make the heart more susceptible to toxic injuries (13).

Disorders of the cardiovascular system are among the most important symptoms of Graves's disease, and in no case, if it is of sufficient duration, do cardiac symptoms fail to appear eventually. A regular tachycardia, usually ranging between 100 and 140, which in severe cases may reach 200, is the most constant manifestation. The rate is not slowed by rest or during sleep, a feature which differentiates it from the functional tachycardias. Slight emotional stress results in a marked acceleration of the pulse rate.

The patients complain of palpitation, precordial pain, pulsations in the neck, head and epigastrium, as well as shortness of breath on exertion. Physical examination reveals an overactive heart, which may or may not be enlarged, with a diffuse strong apex beat. The first heart sound is often sharp and snapping and may simulate the one heard in mitral stenosis. A systolic murmur may be heard at the apex or base. The pulse is full and quick, resembling the pulse in aortic insufficiency. A systolic flushing of the skin may frequently be elicited. The systolic blood pressure is usually elevated while the diastolic pressure is normal or low. Characteristic is the lability of the systolic blood pressure. It varies as does the pulse rate, becoming elevated following physical or emotional stress. In certain cases the blood pressure is low, particularly in patients with marked asthenia, who are in the exhaustion state of the disease.

If the Graves syndrome does not last too long, the heart may be restored to normal. If the disease persists or becomes severe, the cardiac involvement becomes more serious and progressive. At first extrasystoles may appear. More characteristic, however, is auricular fibrillation, which occurs at first in paroxysms but later becomes continuous. Then signs of myocardial insufficiency and stasis in the peripheral circulation become manifest. Once the cardiac involvement has progressed to this stage, the damage is permanent and is not relieved by the arrest of the Graves disease, so that most of these patients die from cardiac failure.

In a recent series of 377 cases of Graves's disease reported from the Mayo Clinic (14), auricular fibrillation was found in 22.4 per cent. In a number of cases the fibrillation followed immediately on operative interference. In the whole series, which was studied electrocardiographically, other irregularities were very unusual. It is interesting to note that abnormal Q R S complexes and inverted T waves, both signs of myocardial disease, were observed in only two cases. A good review of the literature with an analysis of the cardiovascular symptoms in 141 cases studied at the Peter Bent Brigham Hospital has recently been published by Dameshek (15). Early arrest of the Graves syndrome by operation or other means will not infrequently lead to a restoration of normal cardiac rhythm (16). Even when the irregularity has existed for a long period of time sinus rhythm can usually be reestablished by the administration of quinidine, if the activity of the disease has been checked (17).

TREATMENT

Of greatest importance are general measures directed to the control of Graves's disease. In addition it may be necessary to employ specific measures for certain cardiovascular symptoms. In a severe case with an overactive heart, an ice bag to the precordium may be indicated. Digitalis or its derivatives are of no value in the control of the tachycardia before irregularity of rhythm sets in. In the milder cases, when the patient is up and about, exercise must be limited sufficiently to prevent the appearance of dyspnea. When auricular fibrillation and myocardial insufficiency appear, the treatment corresponds to that of ordinary heart disease. It is at this stage that digitalis proves of value. With auricular fibrillation sufficient digitalis should be administered to control the pulse deficit and to reduce the pulse rate to as close to 72 as possible. One must, however, guard against serious cerebral toxic effects of this drug, to which patients with Graves's disease seem to be particularly subject (18). The auricular fibrillation of exophthalmic goitre lends itself particularly well to successful treatment with quinidine hydrochloride.

In myxedema the heart is usually normal. However, Zondek (19) and Assmann (20) have described large hearts in myxedematous patients which rapidly receded in size following the administration of desiccated thyroid. The electrocardiogram of such a heart may show the P wave absent, and the T wave very small (19). Aftertreatment with desiccated thyroid the complexes again become normal. Burlage (21) has made similar observations on cretin sheep. The drug, however, must be given with great caution to these patients, for some of these badly damaged hearts are unable to meet the strain of a too sudden increase of the cellular metabolism of the body. In such cases it is well to start with doses of one half grain of thyroid gland twice a day. If this is well borne, larger doses may be employed (22).

Resection of a Portion of the Axillary Artery*

FREDERICK W. CELCE, M.D.
Philadelphia

Because of its anatomical position the axillary artery is frequently injured and its involvement in neoplastic metastasis is not rare. Its proximity to the surgical field in operative procedures in the axilla seems to make the following case report worthy of presentation.

The axillary artery, the continuation of the subclavian, begins at the lower border of the first rib and has its termination at the lower border of the tendon of the teres major muscle, where it becomes the brachial artery. The line of the artery is straight only when the arm is out from the body; if the arm lies by the body, the artery describes a curve with its convexity outward; if the arm is abducted above the level of the shoulder, the artery curves with its convexity downward. The artery is divided into three parts by the pectoralis minor muscle. The branches of the various parts are 1, highest thoracic; 2, thoracoacromial and lateral thoracic; 3, subscapular, anterior and posterior humeral circumflex. The relations are well known. The axillary nodes are in three sets—one along the edge of the pectoralis major muscle (pectoral nodes) and other further back along the anterior edge of the scapula (scapular nodes) and a third following the course of the axillary artery (the humeral nodes). In our experience, those along the pectoralis major are most frequently involved.

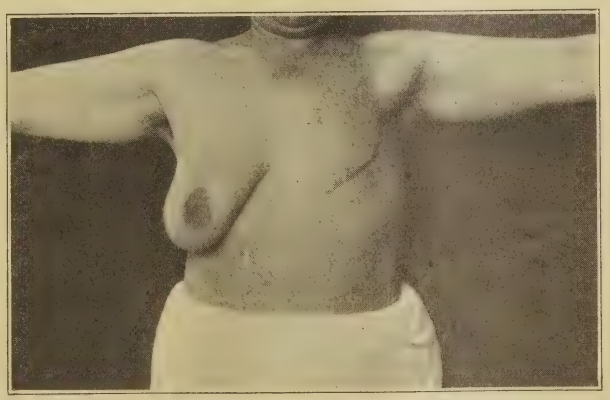

Fig. 1.—Case II. Mrs. B. M., operated upon on May 15, 1925, for carcinoma of the left breast with axillary metastasis. Resection of a portion of the axillary artery. Note symmetry of the arms. This photograph was taken one year after operation.

Injury and involvement of the axillary artery may be due to a number of diverse causes such as aneurysm, gun shot wounds, stab wounds, fractures and dislocations of the humerus, spontaneous rupture from trauma, neoplastic involvement and metastatic glandular involvement. There are many cases reported in the literature of ligation of the artery principally in its first and third portions by reason of aneurysm and traumatic injury. In a careful review of the literature only one case of resection of a portion of the artery came to my attention.

Case I.—This was the case of Private C. J. wounded August 17, 1917 by a rifle bullet. At a point immediately above the crossing of the inner head of the median nerve the artery presented a slight bulging and appeared to be bruised. It was pulsating below this point but on palpation the damaged portion of the wall of the vessel felt thin and a very slight weeping of blood occurred. The artery was ligated above and below and the damaged portion excised (three-quarter inch). There was also nerve damage not relevant here. The authors state "The patient made an uninterrupted recovery and was evacuated to England on August 31, 1917. There was already some return of power in the extensors of the wrist. We have since heard that he is making good recovery." This case and the cases which I will now report are but remotely comparable, as the resection was done in different portions of the artery and also as the former case had nerve damage while the following case had none.

Case II.—Mrs. B. M., white, aged forty, was admitted to the Lankenau Hospital, Philadelphia, Pennsylvania, May 15, 1925. She had an irregular mass in the left breast which she had noticed eight

*From the Department of Surgery of The Lankenau Hospital, Philadelphia, Pennsylvania.

months before admission. This had gradually been increasing in size but at no time was there pain in the breast or any discharge from the nipple. The weight of the patient had remained the same for the past five years. Upon examination the patient had a florid complexion, very foul breath, marked oral infection with pyorrhea and infected stumps of teeth. Her chest expansion was fair and equal. Lungs were clear. There was a large diffuse, hard mass in the upper outer portion of the left breast about the size of an orange. The skin was firmly adherent and was markedly thickened and retracted over this area. The mass itself was adherent to the underlying tissue. Definite axillary nodes were palpated on the left side. The blood pressure was 130-78. Carcinoma of the breast with metastasis was diagnosed and an operation was performed by Dr. John B. Deaver. The pectoral muscles were not removed but the fascia covering them was cut away cleanly. Metastatic carcinoma was found in the axillary glands, a mass on the subclavian vein being freed with difficulty. In dissecting the axilla, a mass firmly adherent to the axillary artery was found lying beneath the pectoralis minor muscle. The artery was ligated and one and one half inches cut away between ligatures. This showed definite metastasis into the wall. An uneventful recovery was made. There was no radial pulse at the left wrist after operation. The temperature after the first two days was normal and the arm remained warm being only one half of a degree colder than the right arm. There was no discoloration or swelling or pain at any time. Upon discharge on May 30, 1925 the patient had almost normal use of her arm and the x ray showed no metastasis to the lungs. Pathological report revealed carcinoma simplex with metastasis. Metastasis in a gland adjacent to the axillary artery invaded the wall of the artery. One year later on May 24, 1926 the patient was again seen in our followup clinic having had x ray therapy in the interim. Then a small palpable nodule under the thyroid muscles in the supra clavicular fossa was discovered. Function has never been impaired, nor, with the exception of the fact that there was no detectable radial pulse at the left wrist, was there any disturbance of circulation. The measurements taken at the time follow:

	Right Arm.	*Left Arm*
1. Half way between elbow and shoulder	26½ cms.	27 cms.
2. Half way between 1. and shoulder	29½ cms.	28 cms.

The collateral circulation established in this case is mainly by the free anastomosis of the subscapular artery with the transverse scapular and transverse cervical branches of the subclavian.

Postinfluenzal Heartblock*

ALBERT S. HYMAN, M.D.
New York

Irregularities of the heart beat arising during the course of the severe infectious diseases (1) have been noted for many years (2) by clinicians. In such serious affections as diphtheria (3), typhus (4) and typhoid (5) fevers, certain types of pneumonia (6), and above all, acute rheumatic fever (7) irregularities of the pulse are discovered quite frequently.

Such irregularities when carefully studied by polygraphic or electrocardiographic methods tend to fall into three great general groups, the first and undoubtedly the most common of which are the premature beats or extrasystoles. The second group would include the gross perversions of the mechanism of the heart beat like auricular flutter or fibrillation. The third, and perhaps the least common because they are more difficult to distinguish clinically, is the group wherein there is depression of the conducting system resulting in heartblock of various degrees of severity.

Heartblock of the socalled first degree where the conduction time for the impulse to pass from the auricles to the ventricles is increased beyond the upper normal limit of 0.20 seconds (8) is sufficiently common in severe general infections as to deserve only passing notice. It is seen especially during the second and third weeks of a diphtheritic infection and the fourth and fifth weeks of a typhoid process.

Heartblock of the second degree, however, with actual dropping out of a complete ventricular systole is not so common and its detection has been considered evidence of serious myocardial damage and an indication for a guarded prognosis.

Recently attention has been directed toward the cardiac involvement following an influenzal infection

*From the Witkin Foundation for the Study and Prevention of Heart Disease at the Beth David Hospital, New York.

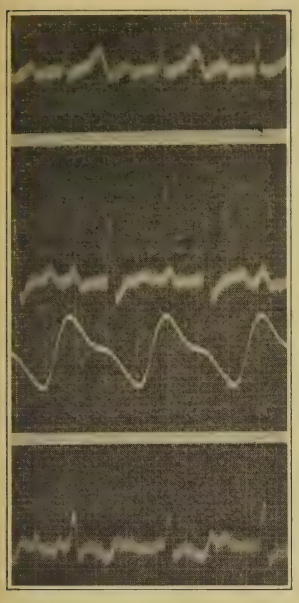

Fig. 1. — Electrocardiographic and polygraphic records taken on December 30, 1925. P-waves well formed and upright in all leads. P-R interval measures from 0.28 to 0.36 seconds. QRS-complexes slightly delayed in conduction time but upright in all leads. T-waves well formed and upright in Lead I; upright but somewhat "bowed" in Lead II; inverted in Lead III. Auricular-ventricular rate 100 beats per minute. First degree of heart-block with severe myocardial damage without disturbance of rhythm.

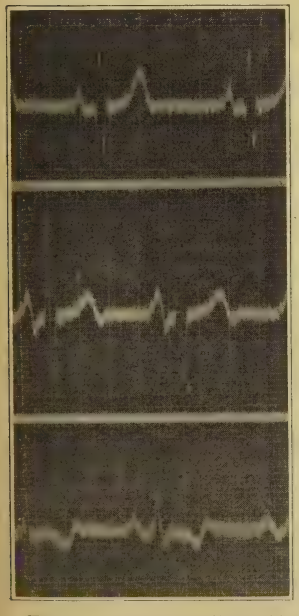

Fig. 2. — Electrocardiographic records taken on January 22, 1926. P-waves well formed and upright in all leads. P-R interval measures 0.20 seconds (the upper limit of normal conduction time); QRS-complexes not delayed and upright in all leads. T-waves well formed and upright in Leads I and II but still inverted in Lead III. Auricular-ventricular rate 68 beats per minute. First degree of heart-block essentially recovered; still residual myocardial damage.

and the observation made by many clinicians in the course of the cases occurring in the past winter and spring's mild epidemic of this disease has done much to include influenza among the group of infectious diseases which leave their imprint upon the heart. Undoubtedly the most striking observation which has been made in regard to the recent outbreak of influenza is that the severity of the actual infection itself is in no way comparable to the subsequent myocardial damage. If any generalization is to be made, most clinicians might be inclined to believe that the cases with the mildest apparent symptoms frequently suffered the greatest cardiac involvement; perhaps the converse of such a general statement would be more accurate in that the cases which showed the most severe cardiac complications ran a rather mild or almost negligible influenzal infection.

While such cases have not been uncommon in our experience, three may be selected in demonstrating certain interesting phases in the development of socalled postinfluenzal heartblock, a phrase which has appeared only recently and which we believe originated with Prof. J. Rehfisch of Berlin in whose clinic we were fortunate enough to see several such cases a few years ago. The cases selected for presentation here are chosen because the original influenzal attack was exceedingly mild while the subsequent myocardial damage was rather severe.

The following case is rather typical and illustrates the development of a first degree of heart-block with depression of the conducting system; such cases usually are accompanied by an associated myocardial involvement which may persist after the conduction disturbance has cleared up. In this particular case both the myocardial damage and conduction system depression were restored at about the same time.

Case I.—F. N., female, aged twenty-eight, married. Family and past history irrelevant. The patient was usually well and active. On December 10, 1925, she arose with a mild headache and a general feeling of malaise. During the day she had a slight fever (100.6° F.) and on the following day she complained of pains and aches throughout the arms and legs. By the evening of the third day she was practically well again and resumed her usual duties, although feeling somewhat weakened. Ten days later after climbing up two flights of stairs she was seized with cramplike pains in the precordium which were associated with extreme dyspnea. For the next few days she was especially heart conscious and when seen four days later she had had several fainting spells.

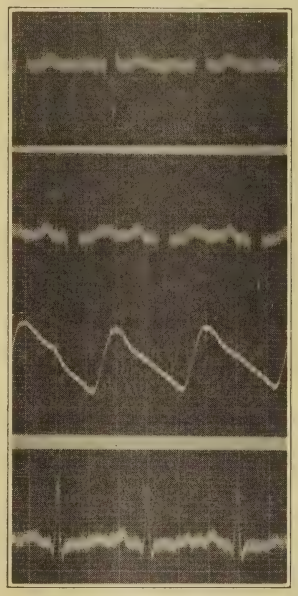

Fig. 3. — Electrocardiographic records taken on May 4, 1926. P-waves upright in all leads; P-R interval measures 0.18 seconds. QRS-complexes upright in all leads. T-waves upright in all leads though somewhat flattened in Lead III. Auricular-ventricular rate 100. Rather normal tracing.

A brief résumé of the cardiovascular study made on December 30th follows:

The patient was a well developed young woman at her normal weight. Under the Dressler white light she showed a suggestion of cyanosis of her mucous membranes. During the course of the examination she had a slight attack of dyspnea. To percussion the area of cardiac dullness was not increased. The apex impulse was located with difficulty in the fifth interspace just within the midclavicular line. It was neither heaving nor forcible. No thrills or shocks were felt. The heart sounds were clearly heard over the entire precordium; at the apex the first and second sounds had about the same tonal quality but at the base, the second pulmonic sound was accentuated over the second aortic. The sound of the valve closures was of good quality. The dominant rhythm of the heart was regular; the apical rate was 100. All of the apical beats were transmitted through to the radial artery. No sinus arrhythmia was detected but other vagal effects like the breath holding test of Rehfisch and the ocular cardiac reflex of Starling were positive. No murmurs were heard. The lungs were clear throughout; no MacKenzie râles were heard at either base posteriorly. Neither liver nor spleen was palpable and there was no free fluid in the abdomen. There was no edema of the lower extremities.

Blood pressure reactions with the Pachon oscillometer gave pulsations from the brachial artery as

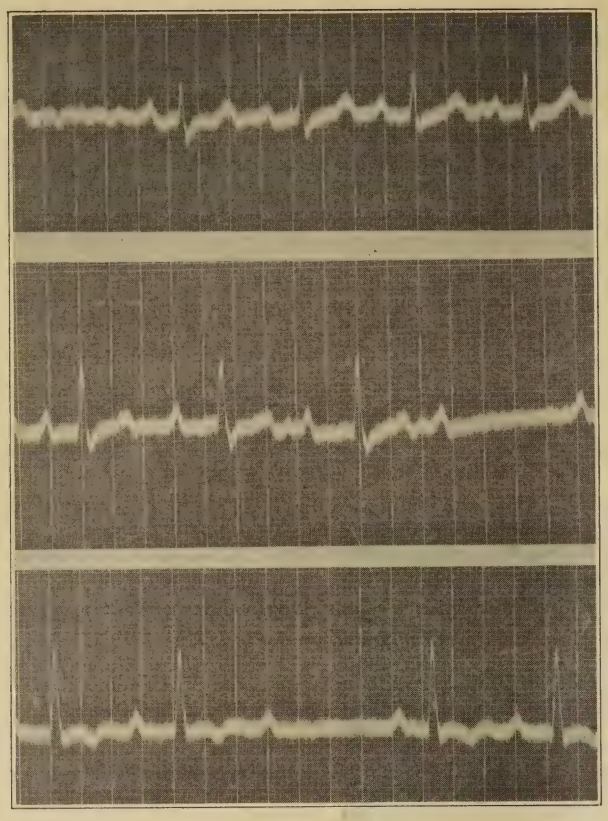

Fig. 4

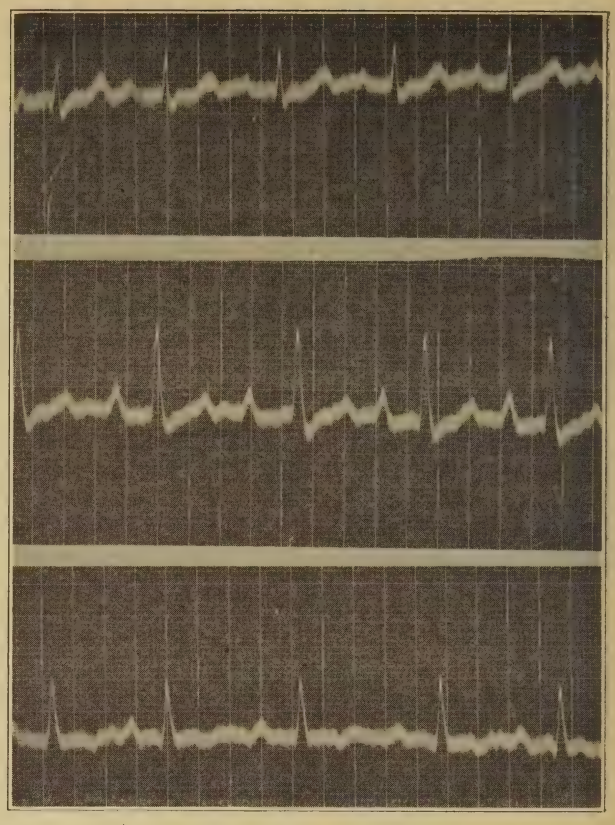

Fig. 5

Fig. 4.—Electrocardiographic records taken on June 6, 1926. P-waves well formed and upright in all leads. P-R interval varies from 0.40 to 0.28 seconds. QRS-complexes upright in all leads but delayed in transmission. Every fifth or sixth complex dropped out. T-waves well formed and upright in Lead I; upright but "bowed" in Lead II; inverted in Lead III. Second degree or partial heartblock with 5:4 and 6:5 rhythm. Severe myocardial damage.

Fig. 5.—Electrocardiographic records taken on June 9, 1926. P-waves well formed and upright in all leads. P-R interval varies from 0.36 to 0.24 seconds. QRS-complexes still delayed but upright; no complexes dropped out. T-waves well formed and upright in Leads I and II but still inverted in Lead III. Auricular-ventricular rate 76. First degree heartblock with severe myocardial damage.

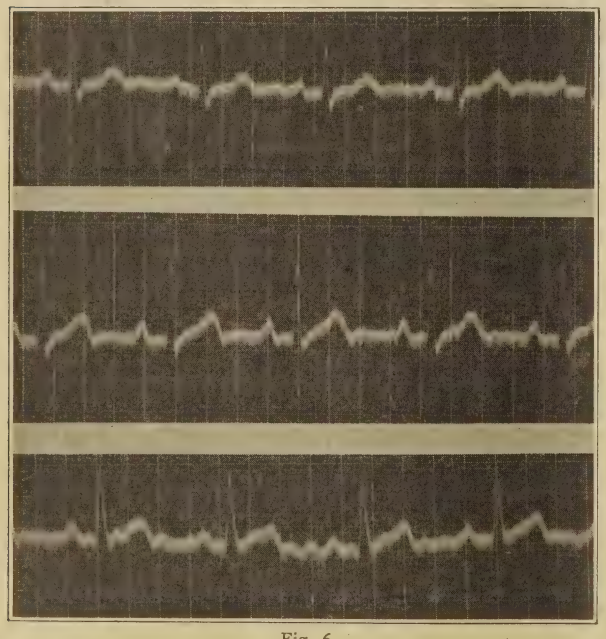

Fig. 6

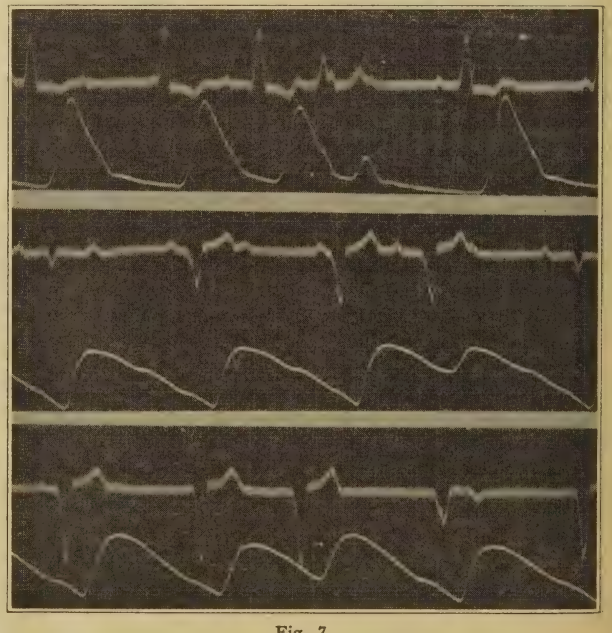

Fig. 7

Fig. 6.—Electrocardiographic records taken on June 20, 1926. P-waves well formed and upright in all leads. P-R interval measures from 0.22 to 0.18 seconds. QRS-complexes upright in all leads but still somewhat delayed in the third lead. T-waves well formed and upright in all leads. Auricular-ventricular rate is 78. Rather normal tracing.

Fig. 7.—Electrocardiographic and polygraphic records taken December 2, 1925. P-waves small but upright in all leads. P-R interval inconstant and often absent. QRS-complexes upright in Lead I but downward in Leads II and III; the complex is greatly delayed in transmission and it occurs in different sizes and bizarre forms. T-waves dominantly inverted in Lead I but upright in Leads II and III; after bizarre complexes it may reverse its isoelectric excursion (i. e., in the first lead it becomes upright and in the third it becomes inverted). The T-waves occasionally coalesce with the P-waves. Auricular rate is about 88 and the ventricular rate is about 40. Third degree or complete heartblock; absolute dissociation of auricles and ventricles with severe myocardial damage, probably also a right bundle branch block.

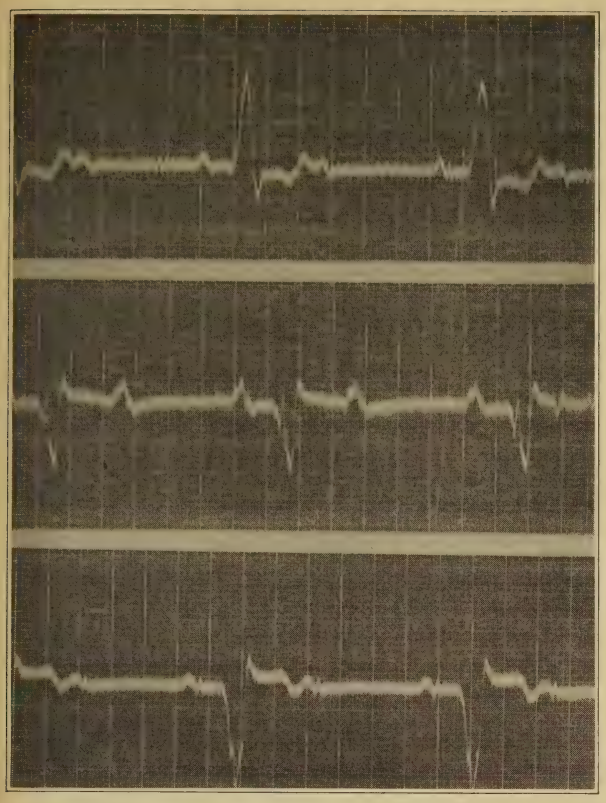

FIG. 8.—Electrocardiographic records taken on February 17, 1926. P-waves well formed and upright in all leads; every second P-wave coalesces with preceding T-wave; there are two P-waves for every QRS-complex. P-R interval measures 0.26 seconds and is practically constant. QRS-complexes greatly widened and delayed with aborization in the second and third leads. The complexes are upright in Lead I but downward in Leads II and III. The T-waves are di-phasic in Lead I and they coalesce with every other P-wave; in Leads II and III they are combined in a bizarre form with the QRS-complex. Auricular rate is 84 and the ventricular rate is 42. Second degree or partial heartblock with a 2:1 rhythm; first degree heartblock with a delayed P-R interval. Considerable myocardial damage. Right bundle branch block.

high as 130 and as low as 70 mm. of mercury. The curve presented was rather normal. Clinical blood pressure levels were established as systolic 124 and diastolic 78.

Vital capacity determinations showed a total expired tidal volume of 1800 c. c. Based upon her weight of 136 pounds this represented a reduction to fifty-five per cent. and based upon her height of sixty-two inches this represents a reduction to fifty-seven per cent. of her theoretical normal standard. (Myers tables.)

Fluoroscopic examination showed the heart to have a rather normal contour; the pulsations and movements of the ventricles and great vessels were normal. The lung fields were clear. The diaphragmatic excursions were equal and of good amplitude upon both sides. No pericardial diaphragmatic adhesions were seen.

Orthodiagraphic measurements showed the heart to be rather small for this age height group. The diagonal diameter of the heart measured 11.5 cm.; the right horizontal measured 3.5 cm. and the left 8.5 cm. The aortic arch measured 4.5 cm. across.

Electrocardiographic studies were interesting. The P-R interval representing the conduction time from the auricles to the ventricles measured from 0.28 to 0.36 seconds in duration; a first degree of heartblock.

Without the electrocardiographic studies the diagnosis in this case might have been impossible as there were no specific clinical signs of this type of heartblock, and for this reason we believe that many similar cases are missed.

The patient was treated rather conservatively with both theobromine sodium salicylate and theobromine calcium salicylate under the Parkinson theory that conduction is enhanced by coronary dilatation. Except for the general weakness which usually follows an influenzal infection the patient had no complaints; she remained in bed until January 16, 1926, and on January 22nd another electrocardiographic study was made.

Further electrocardiographic studies were made upon February 18th, March 30th, and April 21st, but it was not until May 4th that the conduction disturbance entirely disappeared and the time required for the impulse to pass from auricles to ventricles returned to its original normal time of 0.18 seconds.

This case illustrates rather emphatically how persistent the postinfluenzal condition may remain and more especially how severe the postinfluenzal condition may be when compared with the transient and almost evanescent character of the original attack itself. Although the patient had clinically recovered after a very few days, the cardiac affection remained for more than four months.

Such cases are not uncommon but they are usually undiagnosed as the severity of the disease does not warrant or even suggest an electrocardiographic study. In a series of nineteen cases of influenza studied, but not yet published, during the winter of 1925-26, nine were found to have a delayed conduc-

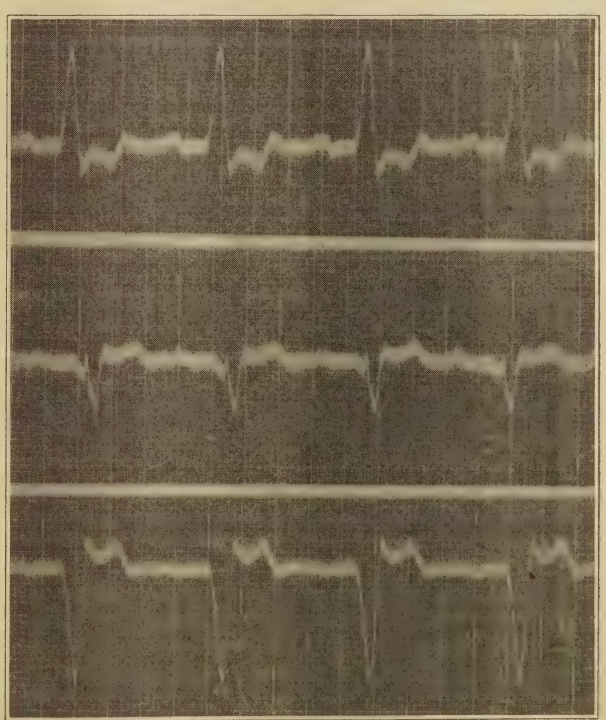

FIG. 9.—Electrocardiographic records taken on April 2, 1926. P-waves upright in Leads I and II but inverted in Lead III; they are not well formed except in the first lead. P-R interval measures 0.28 seconds and is constant. QRS-complexes still greatly delayed in transmission but no longer arborized in Leads II and III. T-waves are well formed in all leads; they are inverted in Lead I but upright in Leads II and III. The auricular-ventricular rate is 66. First degree of heartblock; considerable myocardial damage. Right bundle branch block.

tion time. If this ratio holds good for all influenzal infections, it would appear that a first degree of heartblock is quite common as a sequela to such infections and that the influenza toxin, whatever it may be, may render as much damage to the myocardium as the other better known infectious diseases previously discussed.

Heartblock of the second degree is characterized by rather regular intermissions in the apical beat with a rhythmic jugular pulsation; it can thus be readily distinguished at the bedside from extra systoles and other irregularities of the heart beat. The theories developed to explain the mechanism of the intermission or dropping out of a ventricular beat are manifold (9) (10). Very recently Ashmann and Herrmann (11) have described a recovery curve in the conducting system which brings much new light upon the problem, which though it may appear entirely academic to the general practitioner of medicine, is nevertheless of extreme importance in prognosis (12).

Suffice it here to note that in general heartblock of the second degree is a further and more advanced process than mere delay in conduction from the auricles to the ventricles as in a first degree of conduction depression. The intermissions call attention to the pulse rate in a case which has hitherto shown no unusual cardiac signs. The intermissions may occur in any of several ratios; the most common clinically are 2:1 (i. e., two auricular beats to one ventricular beat), 3:2, 4:3, 5:4 and 6:5. In the following case the ratio varied from 5:4 to 6:5.

Case II.—E. M., female, aged eighteen. Past history of frequent attacks of tonsillitis and sore throats nearly every winter; scarlet fever at the age of eight. Otherwise usually well and attended school regularly. On June 3, 1926, she returned from school complaining of headache and general malaise; she vomited several times and had a temperature of 102.8° that evening. For the next two days she showed a typical influenzal syndrome with the temperature gradually falling to 99.8°. At this time the pulse which had been about 94 suddenly became irregular, so that only 66 to 72 was felt at the wrist.

A physical examination at this time showed a rather well developed young girl with a pallid face but without cyanosis of any kind. To percussion the area of cardiac dullness was not increased; the apex impulse was located in the fifth interspace within the midclavicular line. It was somewhat forcible. The heart sounds were clearly heard over the entire precordium; at the apex the second sound was accentuated over the first and at the base the second aortic had about the same intensity as the second pulmonic. All of the heart sounds had good tonal quality. The dominant rhythm of the heart was regular except for intermissions which occurred every fifth or sixth beat; during the intermission the jugular pulsation was regular. All of the apical beats were transmitted through to the radial artery; the apical rate varied from 66 to 78. After exertion or slight exercise the ratio would change to 10:9, 16:15 and finally a regular pulse would develop and would persist for about four minutes when again the intermissions would recur. The apical rate after such an exercise test would vary from 96 to 110. No murmurs were heard.

The lungs were essentially clear throughout; no MacKenzie râles were heard at either base posteriorly. Neither the liver nor the spleen could be palpated and there was no edema of the lower extremities.

Blood pressure was 126/72. Laboratory reports showed a negative urine; a white blood count of 9,400 with 81 per cent. polymorphonuclears; a red blood count of 4,200,000 with 82 per cent. hemoglobin.

An electrocardiographic study made on June 6, 1926, showed a well marked first and second degree of heartblock with a 5:4 and a 6:5 rhythm.

No medication of any kind was given in this case in order to determine what the natural process of recovery might be. The patient was kept quietly in bed on a rather bland diet of about 1500 calories a day.

On June 9th, it was noted that the pulse had become regular again with a rate varying at the wrist from 74 to 80. An exercise test raised the pulse rate to 128 and it continued to remain regular after the pulse has fallen to 76 beats again. A second electrocardiographic study was then made which showed a restoration of normal auricular ventricular rhythm although a first degree of heartblock persisted with a prolonged P-R interval.

From an ordinary clinical point of view the patient had entirely recovered and she was with great difficulty persuaded to remain under observation until the myocardial damage had disappeared and a normal electrocardiographic tracing obtained. Several studies were made on alternate days until on June 20th, seventeen days after the original onset of the influenzal attack, the P-R interval returned to within normal time limits.

The patient was discharged with advice to restrict her activities for some time to come as her tracings are not yet entirely normal, there remaining a variable P-R interval as well as some widening of the QRS complex.

The case presented illustrates again the unusual severity of the postinfluenzal cardiac involvement compared to the original attack of the infection and the long period of time required for the healing of damaged heart tissue.

The third case[1] is selected to demonstrate the effect of an influenzal infection upon an already damaged myocardium; the patient in 1924 had been diagnosed as a "chronic degenerative myocarditis with hypertension."

Case III.—P. P. S., male, aged sixty-three, widower, seen first on December 1, 1926. He had had a headache, some coryza, and a slight temperature for two days. He presented the familiar picture of an acute influenza which he had apparently acquired from two other members of the family who were also sick. The patient was a rather robust individual for his age; he had a definite cyanosis of his mucous membranes and he became dyspneic on very slight exertion.

To percussion the area of cardiac dullness was much increased toward the left beyond the midclavicular line. The apex impulse was rather feeble and could be located about two fingers outside the midclavicular line. The heart sounds were heard

[1]This case was presented before the Clinical Society of the Beth David Hospital on January 11th, 1926.

with difficulty; at the apex the second sound was much louder than the first and at the base the aortic second was definitely much accentuated over the second pulmonic; the sound of the valve closures was not of good quality. The rhythm of the heart was very irregular; large and small beats were heard in no regular order. The apical rate was about 46 but not all of the apical beats were transmitted through to the radial artery; the pulse deficit varied from 4 to 12. By bending the head in a certain position the great veins of the neck could be readily seen; it was noted that there were about 88 jugular pulsations a minute but that these pulsations were not related in time to the carotid pulsations or the apical beat of the heart. No vagal effects could be obtained. There was a rather loud blowing systolic murmur heard best at the apex but transmitted laterally toward the axilla.

The lungs were full of coarse moist râles and emphysematous sounds. The liver edge was just palpable but the spleen could not be felt. No free fluid could be demonstrated in the abdominal cavity. There was a slight pitting edema of the lower extremities.

Blood pressure reactions with the Pachon oscillometer gave pulsations from the brachial artery as high as 230 and as low as 70 mm. of mercury. The curve described suggested a central resistance to the arterial system. Clinical blood pressure levels were established as systolic 208, diastolic 86.

Vital capacity determinations showed a total expired tidal volume of 2100 c. c. Based upon the patient's weight of 178 pounds this represents a retduction to forty-three per cent. and based upon his height of forty-six inches this is a reduction of fifty-two per cent. of his theoretical standard (Myers tables).

Fluoroscopic examination showed the heart to be considerably enlarged with an aortic configuration; the pulsations and movements of the ventricles and great vessels were quite irregular. The lung fields were somewhat clouded throughout; the diaphragmatic excursions were normal but of poor amplitude on both sides; no adhesions were noted.

Orthodiagraphic measurements showed that both the heart and the aorta were enlarged; the diagonal diameter of the heart measured 16.4 cm.; the right horizontal diameter of the heart measured 6.8 and the left 11.8 cm. The aortic arch measured 10.4 cm.

From the clinical examination, the cardiodiagnosis was somewhat difficult; extrasystoles, partial heartblock, and complete dissociation of the auricular and ventricular rhythms had to be considered. The electrocardiographic studies in this case were quite essential for an understanding of the condition. The first record was made on December 2, 1925.

The severity of the myocardial damage made any therapeutic test inadvisable. Such gross perversions of the mechanism of the heart beat respond poorly to the usual methods of treatment. Adrenalin has been used more or less successfully by Parkinson at the National Heart Hospital in London and the author had an opportunity to watch three such cases under treatment at this institution in 1924. Meyer (13) believes that atropine gives more permanent relief than adrenalin; recently barium chloride has been used with promising results (14).

Sir James MacKenzie at one of his last appearances in London in 1924 told the author that he believed alcohol to be of considerable value in most conduction system disorders; in spite of the controversial opinion in regard to alcohol now in vogue, the patient was given small amounts of whiskey three or four times a day over several weeks with a gradual but not continuous improvement in the cardiac rhythm.

On February 14th, for the first time in about ten weeks, the radial pulse became regular with a rate of 42. The jugular pulsations could easily be counted at 86. A second electrocardiographic study was made on February 17th.

The patient was then permitted to become somewhat more active and theobromine calcium salicylate was administered in daily doses of twenty-one grains. The slow pulse persisted even after exercise of a moderate kind but when seen again on March 26th the pulse rate had increased to 66 beats per minute; there was no pulse deficit and all of the jugular pulsations coincided with the apex beat.

A third electrocardiographic study was made on April 2nd.

Although still presenting gross myocardial damage and with the right bundle branch block still persisting the final cardiac picture is infinitely better than that following the influenzal infection. This case is remarkable in suggesting the successive steps through which the myocardium and conduction system passes when recovering from massive damage. It also demonstrates rather nicely the development of the various grades and types of conduction system depression.

The slow recovery, here about four months after the original attack, once more emphasizes how out of proportion the original infection may be compared to the subsequent extent of the myocardial damage sustained.

SUMMARY

1. Three cases of heartblock demonstrating the various degrees of conduction system depression subsequent to mild attacks of influenza are presented.

2. Heartblock of the first degree with delay in the conduction time from the auricles to the ventricles is seen not infrequently accompanying or following the severe acute infectious diseases of which group influenza must be considered as having a place.

3. Heartblock of the second degree with intermission of the pulse because of dropped beats may follow a mild attack of influenza.

4. Heartblock of the third degree with complete dissociation of the auricles and ventricles may occur in an already badly damaged heart as a result of an influenzal infection.

5. Myocardial damage subsequent to influenzal infection bears no relation to the severity of the original attack; in our experience, the mild or skipped cases have shown the most severe cardiac complications.

6. Electrocardiographic studies of all cases suspected of having myocardial involvement following influenzal infections is suggested.

7. Influenza is to be grouped among other acute infections which leave their imprint indelibly upon the heart muscle and conducting mechanism.

The Treatment of Hypertension

ROBERT HUGH ROSE, M.D.
New York

In many cases of hypertension the diastolic blood pressure may be reduced an average of fifty per cent. of its advance above 80 and the systolic about fifty per cent. of its advance above 120 mm., i. e., a diastolic of 110 can be reduced to 90, approximately; a systolic of 200 can be reduced to 160, approximately. After reduction the pressure can generally be maintained at the lower point. This does not refer to patients in a terminal stage of Bright's disease or other equally serious conditions. It does, however, include some patients apparently in a very bad way and it also includes some cases of extremely high pressures—as high as 250 or more, systolic.

These statements are based entirely upon personal experience. The patients were mostly overweight. Many of them were middleaged, but they include a few older patients, some even above seventy. The literature on hypertension is pessimistic. Much of it deals with hospital cases altogether. The treatment generally described consists of medicine to act on the arteries and does not reach the cause. Treatment which I have used consists of diet, internal secretions, and attention to focal infections including the gastrointestinal tract.

Occasionally the literature contains statements which corroborate the conclusions of this paper. Dr. A. H. Terry, Jr. (1), referring to a group of obese patients treated in the outpatient department of the Presbyterian Hospital, said: "The majority of fat women who seek medical attention have hypertension. The hypertension is usually without findings suggestive of nephritis, diabetes or syphilis. On a high protein, low calory diet there is a lowering of weight, together with a lowering of blood pressure and this frequently relieves the chief complaints."

Dr. Eugene Lyman Fisk (2), in an analysis of 17,000 cases examined under the auspices of the Life Extension Institute, while he found no preponderance of hypertension among smokers or those on a high protein diet, did find, in a group of 2,145 overweight patients, hypertension in 14.9 per cent., contrasted with only six per cent. in a group of persons of normal weight. He says, "It is not at all uncommon to find a fall in blood pressure one millimetre per pound as the weight comes down by diet and exercise." Dr. Fisk (3), in collaboration with Louis I. Dublin and Edwin W. Kopf, found that in the ages of forty-five to fifty-four those persons twenty per cent. or more above normal weight showed, as compared with those of normal weight, approximately two and one half times as many with systolic blood pressure 20 to 60 mm. above normal and five times as many with 60 or more mm. above normal.

Hypertension is a symptom. Its cause should be found and treated just as is done with the symptom fever. Overweight, or the diet which produces overweight, would seem to be a cause in many cases and should, therefore, be treated. The chief contraindication to the reduction of high blood pressure is thickened narrowed arteries with signs of failing circulation. Here hypertension is the lesser of two evils. If reduced it might hasten a stroke or impair the circulation in an extremity.

The first observation of the writer on the dietetic treatment here outlined was made while reducing weight for a very stout patient. Thereafter the point was followed up and it was found to be the rule that reducing weight also reduced blood pressure. As the general condition of the patient was at the same time improved it was used for patients with the slightest amount of excess adipose tissue. No vasodilators were used. Results have remained up to seven years, i. e., as long as these cases have been under observation. Only those patients with distinct organic lesions failed to respond.

Case I.—Mrs. R. G., aged forty-five, first seen on February 23, 1926. She complained of headaches, swelling of the hands, pain in the knees, wrists and shoulders, shortness of breath, rushing sound in the ears, hot flashes and insomnia. She had not been well for six years and had spent ten months in bed—three weeks of which were in a hospital. According to her statement her blood pressure at one time ran from 280 to 300. On examination the patient's pulse was found to be 108, and her blood pressure, diastolic 110, systolic 232 to 238. The skin was very dry; hair dry and harsh; weight 146 pounds; a large proportion of the weight was carried about the trunk and waist.

This patient was placed upon a treatment combining a use of diet with glandular products. Injections of corpora lutea and thyroid tablets were administered. A cathartic containing bile salts was used with occasional doses of epsom salts. During this treatment a weight reduction diet was followed. This consisted chiefly of milk, coarse, green vegetables, and fruit.

March 1st: The patient showed the following record: Pulse 96; blood pressure, diastolic 104, systolic 212 to 218; weight 141 pounds.

March 6th: Pulse 84, blood pressure, diastolic 106, systolic 190; weight 138 pounds 12 ounces. The same treatment was continued with the exception that she was given ovarian instead of thyroid tablets. This was done because the insomnia, though somewhat relieved, was not entirely gone.

March 20th: Pulse 72, blood pressure, diastolic 96, systolic 168; weight 136 pounds 4 ounces. The patient was sleeping better. The tablets were changed back to thyroid. Many of the symptoms were by this time relieved; including the pain in the joints, shortness of breath, swelling of the hands, headaches and to some extent the head noises and insomnia.

September 20th: The examination was as follows: Pulse 78, blood pressure, diastolic 96, systolic 170; weight 130 pounds. Some of the noises in the head, insomnia and some pain over the cardiac area had been complained of during recent visits. An x ray of the teeth shows apical abscesses and extractions were ordered.

Result: In twenty-five days the pulse was reduced

from 108 to 72; diastolic pressure from 110 to 96; systolic pressure from 238 to 168 and weight from 146 to 136 pounds. Six months later the pulse was 78; diastolic 96; systolic 170; weight 130.

CASE II.—Mrs. E. T., aged fifty-five years; first seen April 20, 1926. The patient complained of dyspnea; palpitation; pulsation in the neck; nervousness; pain in the finger joints; high blood pressure had been discovered. On examination the patient showed the following: Pulse 84, blood pressure, diastolic 150, systolic 240; weight 150 pounds. Urine was negative for albumin, sugar and indican; specific gravity 1010; pus was pressed from tonsils; marked pulsation was visible in the arteries of the neck.

The following treatment was instituted: Injections of corpora lutea and tablets of ovarian substance; throat gargled with iodine solution. Diet was prescribed consisting of bacillus acidophilus milk, coarse vegetables and one potato daily.

April 23rd: Pulse 80; blood pressure, diastolic 120, systolic 210 to 214; weight 149 pounds 8 ounces.

April 28th: Pulse 80; blood pressure, diastolic 120, systolic 200; weight 148 pounds 11 ounces.

April 30th: Pulse 76; blood pressure, diastolic 116, systolic 188; weight 148 pounds.

May 18th: Pulse 72; blood pressure, diastolic 100, systolic 160; weight 145 pounds 12 ounces. Tablets were changed to thyroid. All symptoms were marked relieved, including buzzing in the ears and shortness of breath.

August 11th: Pulse 84; blood pressure, diastolic 112, systolic 168; weight 148 pounds 12 ounces. This reading was made after the patient had not been seen for two months. Previous treatment was again instituted.

Result: In four weeks, diastolic pressure was reduced from 150 to 112, systolic from 240 to 160; weight from 150 to 145 pounds 12 ounces.

The following case is presented because of the remarkable effect of diet and cathartics upon what seemed to be a very serious heart condition. This is a case of cardiac incompensation. It corresponds to what Dr. Arthur R. Elliott (4) describes as high blood pressure stasis. At first the heart is able to keep up a high pressure but as it comes to a time when it is embarrassed thereby, a degree of stasis is developed in the bloodvessels.

CASE III.—Mrs. H. A. G., aged seventy, first seen May 27, 1922. She gave a history of dyspnea on exertion for two years. At the time of the first visit she was unable to lie down because of dyspnea, being compelled to sleep sitting in a chair, and could not walk without embarrassed breathing. She complained of pain in the back of the head. Pulse was so irregular that it suggested fibrillation. Blood pressure, systolic 220. The abdomen was greatly distended with gas. Meat had been withheld from the diet for over a year because of the blood pressure.

The patient was placed on a diet consisting of milk, three to four glasses daily, fruit, green and coarse vegetables. A laxative of bile salts with cascara was used frequently until the abdominal distention was under control. In two weeks' time the pulse had dropped to 72; was much less irregular, and the systolic blood pressure was 210. The patient felt much better; was able to walk four blocks, and could sleep lying down. Her weight was then 153 pounds eight ounces, having dropped from 160 pounds.

Two and a half weeks later, on June 28th, her blood pressure was, diastolic 104, systolic 190; weight 146 pounds. Diet was limited to fruit, milk, green and coarse vegetables. At this time salt was also excluded. She was comfortable and able to walk a considerable amount. Improvement continued and on July 9th, pulse was 60; blood pressure, diastolic 98, systolic 166; weight 143 pounds. The patient was able to walk twenty blocks without difficulty; seemed entirely recovered and in excellent condition for one seventy years of age. A short time thereafter she was able to walk up hills with ease. Diet advised as follows: One pint of milk daily; meat once a day —small helping; egg occasionally; fruit; coarse and green vegetables. Heavy starches and fats limited to quantity sufficient for maintenance of weight. On July 7, 1924, I received a letter stating that the patient had done well except once or twice when she had given up the diet.

Result: In two months weight was reduced from 160 to 143 pounds; diastolic from 115 to 98; systolic from 220 to 166; pulse from rapid, irregular, to 60 and regular. This patient was a woman seventy years of age and she was well when last heard from in 1925.

I have selected five cases and arranged a table showing the reduction in pulse, diastolic blood pressure, systolic and weight. The average reductions were as follows: pulse 25; diastolic 22, systolic 66; weight 11 pounds.

A table of thirty-five cases was also arranged. This showed the following average reductions: pulse 17; diastolic pressure 20; systolic 39; weight 16 pounds.

The treatment was according to the following plan: The patients were placed upon a weight reduction diet until results were obtained. Then the diet was increased until weight was just maintained. Cathartics were used rather freely. Focal infections were treated. Preference was given to diet unless it was considered that focal infection was causing marked absorption. Many of these cases received internal secretions. Latterly, evidence of the need of internal secretions was searched for and they were used when indicated. Ovarian, thyroid and liver products were found most useful.

FIVE CASES WITH RECORD OF PULSE, BLOOD PRESSURE AND WEIGHT

	Age	*Date*	*P*	*D*	*S*	*Wgt.*	*Date*	*P*	*D*	*S*	
1	60	Sept. '22	116	100	224	156	Sept. '26	84	90	150	132[6]
2	50	Feb. '19	96	110	230	150	July '26	84	90	170	160
3	70	May '22	Rap & Irreg.	115	220	159	Sept. '22	72	94	180	137
4	45	Feb. '26	108	110	238	146	Oct. '26	68	100	160	129[6]
5	55	Apr. '26	84	150	240	150	May '26	72	100	160	145[12]
Total	280		404	585	1152	761		380	474	820	704
Average	56		101	117	230	152		76	95	164	141
Average reduction								25	22	66	11

P=pulse. D=diastolic blood pressure. S=systolic pressure.

AVERAGES BEFORE AND AFTER TREATMENT IN THIRTY-FIVE CASES

	P	*D*	*S*	*W*	*Duration of Treatment*	*P*	*D*	*S*	*Weight*
Average	94	109	190	182	9 days to 7 years	77	89	151	166 lbs.
Average reduction					.....	17	20	39	16
Greatest reduction					.....	..	..	80	..
Smallest reduction					.....	..	..	14	..

CONCLUSIONS

1. The writer's experience, confirmed from other sources, shows that weight reduction is accompanied, as a rule, by blood pressure reduction.

2. About fifteen per cent. of persons overweight have high blood pressure, according to Life Extension Institute records.

3. In thirty-five cases, the average reduction of diastolic was 20, systolic 39; pulse 17 and weight 16 pounds.

4. Average reduction of blood pressure is approximately fifty per cent. of the increase above normal.

5. Results are best in cases of recent development.

6. Symptoms of dyspnea, palpitation, pulsation in the ears and headaches are relieved. Beginning cardiac incompensation is benefited.

7. No claim is made for reduction of high blood pressure in cases accompanying Bright's disease, although in some cases albuminuria due to congestion of the kidneys disappears.

8. Treatment consisted of weight reduction diet, internal secretions and cathartics and attention to focal infections.

A Consideration of Blood Pressure

ELLICE McDONALD, M.D.
Philadelphia, Pa.

In all studies of blood pressure there has been consideration of only two kinds, higher or lower than normal. As a result of this, the blood pressure estimation has not been of full use to the medical profession because of the impossibility of translating it into terms of vital processes. If any clinical test cannot be translated into terms of vital processes, its value is *nil*.

Blood pressure is an expression of energy or force, of which the human energy machine is the apparatus for production or modification, exactly as a motor modifies the gasoline fuel into energy. Blood pressure, being then an estimation of energy, there must be the two factors which are always present in any energy estimation, the quantity factor and the intensity factor. If water passes through a hose, its flow depends upon the size of the hose and the pressure. If the hose is bigger, the flow is with less pressure and any modification is possible with alteration in these two factors.

With blood pressure there is possible any of the following four deviations from normal:

	BLOOD PRESSURE				
Class.....	I	II	III	IV	
Quantity	+	+	—	—	Heart and blood flow
Intensity.....	+	—	+	—	Vessels and capillaries

In this scheme the heart capacity and blood flow mostly determine the quantity and the tone of the vessels and capillaries, and the resistance of the tissues mostly determine the intensity. These four classes of blood pressure deviation are each different from the other and classes number two and number three are by no means the same.

It is possible to recognize these variations clinically. Class I, with both factors plus, is a type in the high blood pressure of socalled essential hypertension with associated albumin and granular casts in the urine. This class in such cases is associated in my experience with a p.H. of the blood plasma upon the alkaline side of p.H. 7.38. There is generally a full red blood cell count and a rather increased percentage of polymorphonuclear leucocytes. Generally this type seems to be associated with an increased nonprotein nitrogen, although I have not been able to correlate completely the nonprotein nitrogen with the p.H. and the increased blood pressure. The socalled blood chemistry in my hands has been difficult to correlate with vital conditions and this is, I believe, due to the fact that most of such socalled blood chemistry does not take into consideration the fact that the blood is a heterogeneous system where the cells exist as particles in a liquid medium, and the important factors are the potential differences and ionic interchange across the cell surface. It is for this reason that the hydrogen ion estimation of the blood plasma is of such importance and use. It is to me the most valuable test in medicine.

A second limitation to socalled blood chemistry is the fact that the normal balance of the blood plasma is not at p.H. 7., or neutrality, but lies somewhere between the univalent substances and the bivalent and trivalent substances and anions. Sodium and potassium, univalent substances, produce alkalinity, but calcium and magnesium, bivalent substances, produce acidity. The acid cells exist in the alkaline medium and the important facts are the potential differences and tonic interchange.

Again in the cell and the plasma of blood, the chemical ingredients are unevenly distributed. There is about thirteen times as much calcium in the cell as there is outside it, and there is very much more sodium in the plasma than in the cell and so it is with the other ingredients. For this reason the socalled blood chemistry of whole blood gives very little information as distribution and ionization are more important than total amounts.

The high blood pressure of Class I is essentially a preponderance of the sympathetic side of the vegetative nervous system (the epinephrine experimental type) and is in my experience associated with a p.H. of the blood plasma upon the alkaline side of normal. For this reason, as it is an expression of the alkalinity mostly associated with the monovalent substances, it is benefitted by the salt free (sodium free) diet and by the addition of calcium to produce a normal p.H. In addition such acids as hydrochloric acid, phos-

phoric acid and ammonium chloride (which releases HCl and urea) seem to be of use. Various kinds of calcium salts have been tried; the present one most popular with me is a colloidal calcium, although the lactate and formate are also useful. Iodine in very small doses (or thyroxin in very small doses) is of value. In my hands, after an experimental trial of three different preparations, liver extracts alone gave very disappointing results. Liver extracts apparently are sometimes a mild vagus stimulant, and there are many other vagus stimulants, and the fact that its constitution is so inexact, does not incline me to try it again.

In the diet, it should be remembered that bread contains considerable sodium. In my opinion, most of the evils of meat in these cases result from the salt (sodium) eaten with it. There is no effort on my part to completely eliminate meat from the diet. The vitamine A substances without sodium, with elimination of sodium laxatives, is the basis of advice as to diet.

In the study of these cases of Class I (the sympathetic preponderant type of blood pressure), the diastolic pressure is of considerable value in watching the course. A rising diastolic pressure is significant even before any change in the systolic pressure.

Moot's rule: pulse pressure÷diastolic pressure=0.5 where this figure represents the normal, is of value in this Class I and in Class IV, but it is of less value in Classes II and III. This rule is of great value in estimating the resistance before a projected surgical operation or some such effort. Class I is so often the type of blood pressure associated with age, as age, in my experience is so often associated with a p.H. on the alkaline side.

Class IV is the low blood pressure of preponderance of the vagus side of the vegetative nervous system and is commonly associated with a p.H. upon the acid side of p.H.=7.35. A type of it is the low blood pressure of the asthmatic with an acid (less alkaline) p.H. It is so often associated with cardiac inhibition from excess of vagus influence.

Unduly low blood pressure is, in my opinion, quite as important an evil as high blood pressure. We are more apt to stress the high blood pressure because it is a frequent concomitant of a terminal alkaline age condition. Unduly low blood pressure is more frequent in the adult age, and more difficult to benefit.

Blood pressure balance is an evidence of vital equilibrium and life itself is an equilibrium. This equilibrium depends upon chemical forces. The constant body temperature in health is an example of this equilibrium produced by foregoing chemical forces. Disease is a deviation from this equilibrium and predisease deviations must come before disease, the terminal result, ensues. For this reason the equilibrium of blood pressure is important as an index of vital conditions and a low blood pressure is equally a manifestation of disturbance as a high one. The value of blood pressure manifestations is enhanced by correlation with other tests of vital activity such as the hydrogen ion concentration of the blood plasma, the urine examination, etc. Estimation of heart output or capacity would be of great value if accurate, but there seems to be doubt as to the accuracy of all methods of measuring the heart capacity.

Class II is a condition frequently seen in fatigue states and Class III is exemplified by aortic regurgitation with Corrigan's pulse. Class III frequently has swings over to the high side and it may be that this is one method of the production of cerebral hemorrhage—the simple bursting of the vessel does not explain the change. Westphal and Bar (1, 2), in a study of sixteen cases of apoplexy (mostly from hemorrhage) believe that the primary condition is an angiospastic spasm and that the restitution of the blood flow entails the hemorrhage which is coincident with a paroxysm of higher blood pressure. The local anemia from the arterial spasm is, they believe, the predisposing cause and they found lesions in the bloodvessels amounting sometimes to necrosis.

The hemorrhage from the cerebral vessel may be described as a primary alteration in the vessel wall as a result of colloid cell change which causes such changes in the vessel cell wall lattice as to allow diapedesis of blood cells and other colloid produced with increasing blood pressure. This is a possible explanation of such cerebral hemorrhages as occur in Class III with relatively low blood pressure but with swings toward the higher side and often with very high paroxysms.

A very interesting explanation of the blood pressure function, and one that coincides somewhat with that given here, is by Lenaz (3) who regards blood pressure as a function of the water content of the blood and that this is an equilibrium between the colloidal pressure of the blood plasma and the hydrodynamic pressure of the capillaries. He uses red blood cell count (per c.mm.) as an indicator of the water content of the blood: with a rise in capillary pressure the blood becomes thicker. He established a ratio between the blood pressure in mm. and the red blood cell count per c.mm.

This explanation is interesting, but not complete. Any explanation of blood pressure must be able to satisfy the mechanism of the following: (1) heart force; (2) heart capacity; (3) capillary pressure; (4) amount of blood; (5) colloidal water of cells of vessels as well as of blood; (6) hydremia or water dilution of blood as distinct from colloidal water; (7) colloidal aggregation or dispersion of the blood proteins. In such a consideration must be correlated the influence of the sympathetic and vagus side of the vegetative nervous system and the influence of the change of the inorganic substances in producing alteration in the colloids and colloid cells. In such a study, there remains the fundamental fact that blood pressure as an expression of force or energy, capable of measurement, must have two factors, that of quantity and that of intensity. These two factors must be considered in any study of force or energy, and it is to be hoped that a consideration of them will aid in the study of blood pressure, and this study, to be worth while, must be correlated with the vegetative nervous system and with colloidal changes in the blood and in the body. In this way only will such a study be of value and knowledge be gained of the equilibrium of life of which the blood pressure balance is one example.

Mercury Quartz Lamp in Cardiology

JOSEPH ECHTMAN, M.D.
New York

For a more comprehensive appreciation of the idea expressed in this article, a brief review of the physiology of the cardiac beat and of the present theories of the action of quartz light upon metabolic disturbance of calcium is important.

THE PHYSIOLOGY OF THE HEART BEAT

The chief inorganic salts found in the body are chlorides, phosphates, sulphates and carbonates of sodium, potassium, calcium and magnesium. Iron is present in a small amount. Sodium, potassium and calcium have jointly a favorable effect upon muscular contraction, notably upon that of the heart beat.

The perfused fluid most commonly used for successful resuscitation of the heart beat in an artificially perfused heart is the socalled Ringer's solution containing sodium, potassium, and calcium chlorides in certain proportions. Both calcium and potassium in the fluid seem to be essential, the former favoring contraction and the latter relaxation. If the proper balance of these salts is present in the fluid regular contractions and relaxations of the cardiac muscle will take place. The addition of glucose materially improves the nutritive qualities of the perfusing fluid.

It is evident, therefore, that inorganic salts (and probably sugar) are most necessary for the normal action of the heart in the living body.

When the body becomes demineralized a diseased state of the heart, lungs and probably other organs may ensue. We know today that demineralized, chiefly decalcified, patients suffer from a derangement of metabolism of calcium. The usual recalcification by diet and administration of calcium salts may not be of value in such patients until this derangement of metabolism is corrected, otherwise the ingested calcium will not be utilized by their bodies. In their metabolic studies Orr, Holt, Wilkins and Boone (1) show that patients suffering from derangement of calcium metabolism fail to retain calcium and phosphorus, although an adequate amount is present in their diet. The employment, however, of ultraviolet radiation causes large amounts of these elements to be retained in the body because calcium metabolism is influenced greatly by "exposing the patient to the biologic or aircooled ultraviolet rays which induce in the body whose skin surface they strike an increased metabolism of calcium" (Pacini).

THE THEORIES OF HOW ULTRAVIOLET RADIATION AFFECTS CALCIUM METABOLISM. THE SYMPATHETIC NERVE STIMULATION THEORY ACCORDING TO PACINI (2)

Metabolism of calcium is specifically influenced by the sympathetic nervous system whose terminal filaments end on the skin surface and respond to externally applied stimuli, but not to all. It is known, however, that they respond to the region of ultraviolet rays isolated by Pacini and separately by Hess. This response may have to do with the corpuscles of Pacini which are known to respond to thermol influence. Stimulation of the sympathetic through these nerve endings favors calcium metabolism. Therefore, when the little penetrating ultraviolet radiation strikes the skin the energy stimulates the sympathetic nervous system resulting in an increased calcium metabolism.

It is the opinion of others that the quartz rays stimulate calcium metabolism simply through direct stimulation to proper activity of the thyroid and parathyroid bodies whose control over calcium metabolism is an established fact. Lorand (3) assures us that judging from his large experience with ultraviolet rays the latter stimulate the endocrine glands, especially the thyroid. The reports of Grant and Gates (1) on the effect of ultraviolet rays in connection with calcium metabolism on normal rabbits show that the parathyroid glands of the rayed animals were thirty-two per cent. heavier than those of the controls. Blood calcium increased about 12 milligrams p.100 centimetres in twenty-two days of daily radiation. According to the observations of Novak and Hollander (1) calcium alone does not improve calcium metabolism. Calcium with thyroid extract affords temporary improvement in calcium metabolism. Calcium and thyroid medication together with quartz radiation appear to fix permanently calcium metabolism. I have reason to believe that calcium salts, without thyroid[1] but conjointly with quartz radiation administered for a long period, are sufficient.

Quartz radiation influences beneficially not only the calcium content but also the iron and sugar content of the blood. Humphris (4) states that the iron content of the blood is increased and Alpern (1) reports that the sugar in the blood is increased as the result of quartz light radiation.

In view of such important changes produced by quartz light in the blood chemistry, i. e., enriching it in calcium, iron and sugar, substances most necessary for the nutrition of the heart muscle, quartz light, logically, becomes an important modality in cardiology.

Calcium and iron are elements the heart needs for perfect activity, and Osborne (5) named them as cardiac nutritives; the same is applied to sugar. Goulston (6) of London remarks that sugar is of great value in any case where there is reason to believe that the musculature of the heart is failing. Nature seems to regard sugar as a heart nutritive: physiologists have noticed that there is a remarkable amount of glycogen in the sinoauricular node and the auriculoventricular bundle and its connections. We also know that the addition of sugar (glucose) materially improves the nutritive quality of the solution for the artificially perfused heart.

CARDIAC CONDITIONS IN WHICH QUARTZ THERAPY AND NUTRITIVES ARE INDICATED

In the treatment, therefore, of disturbances of the heart these cardiac nutritives should be employed along with quartz therapy. I have noticed that this

[1]In disturbances of the heart thyroid, if chosen for any reason, must be used with greatest caution or not at all.

armamentarium—quartz light, calcium salts, sugar[2] and iron conjointly used[3] is of decided benefit in the following cardiac conditions:

1. Patients with affection of the myocardium where there is a continuously increased heart rate (tachycardia). MacKenzie (8) states that one of the fundamental causes responsible for myocardial affections is a deficiency in some nutrient. This fundamental cause is often overlooked. Of course the various foci of infection must always be looked for in any form of treatment of any cardiac condition. These foci may be, as pointed out by Matthes (9), in the teeth, tonsils, gallbladder, rectum (not included by Matthes), female generative organs, prostate or appendix. Other possible causes which would exclude myocardial affection should be kept in mind, such as neuroses, masturbation in young people, etc. "But there is a series of cases in which it is difficult to account for the rapid pulse especially when it occurs in the apparently strong and in the prime of life" (8). Many patients of this group are greatly benefited by the treatments outlined above.

2. Cases of irregularity of the heart beat with premature contractions (extrasystole). Lewis (10) says: "The presence of premature contractions is an indication of a local disturbance of cardiac nutrition whether temporary or permanent."

3. Rheumatic endocarditis of recent development with mitral insufficiency.

4. Functional disturbances of the heart.

MODE OF GIVING THE TREATMENTS

The patient is at first exposed to radiant heat. The body is just warmed, not heated, as heating the body in cardiac conditions is not advisable. This is followed by a careful and gentle massage in the following manner: legs and thighs are massaged from toes upward, the trunk from the neck down and from side to side. Abdomen following the anatomical course of the intestines using a circular stroke. This procedure relaxes the patient, stimulates peripheral circulation and is very useful, especially in cold weather. The importance of this preparatory treatment is obvious if we consider that the ultraviolet radiation penetrates only a short distance. Furthermore, it is through the cholesterol contained in the skin through which important changes take place during quartz radiation. The activated cholesterol is taken up by the peripheral circulation and through this by the general blood stream and distributed and fresh unactivated cholesterol brought to the surface (Hess, 1).

After the peripheral circulation has been stimulated by radiant heat and massage the quartz light treatment proper is started. Radiation of the entire body is necessary. Here a point of caution is important. According to Levy (1) general irradiation of the whole body at the first sitting may lead to dangerous visceral engorgements. It is therefore sound practice, when general irradiation is intended, to commence by fractional exposures, at each sitting exposing a fresh part and increasing the exposure of previously treated regions until the whole body may be irradiated. Another important point is not to burn the cardiac patient, a first degree erythema[4] being enough for the first two or three treatments on the same region. During the subsequent treatments a second degree erythema[5] is given and never stronger throughout the entire course. A distance of thirty to twenty-four inches from burner to patient is suitable in most cases. Treatments are given twice or three times a week for a period of three to six months with some rest intervals. In the obese cardiac the erythema may be stronger. It may also be given stronger over the precordium, if the patient complains of pain in that region.

It should be noticed that the time and distance to produce a given erythema depend upon the reaction of the patient to the quartz rays. This reaction differs with various patients. There are in fact patients who react comparatively little to the quartz rays. Each patient is a case for itself, and in quartz treatments, as well as in other treatments, the use of good judgment is highly important.

REPORT OF CASES

Case I.—Mrs. Y., aged thirty-eight, suffering from heart trouble, came to my office in November, 1923. She complained of dyspnea, difficulty in walking a couple of blocks, especially walking upstairs, and said she was unable to carry any weight for a short distance without experiencing some exertion. There were no interesting points in her past history except her occupation, as a girl, of cigarmaker.

Physical examination: Tonsils in bad condition; teeth in very bad shape, bridged, capped, pyorrhetic; lungs negative; visceroptosis, umbilical hernia (wearing an abdominal supporter for many years); heart apparently enlarged, rate 120, extrasystols of which she seemed to be very conscious for she said that her heart was "moving like," "throwing itself" and some other peculiar sensations. There was a systolic murmur at the apex.

The urgent necessity of fixing the teeth was impressed upon the patient, who, in turn, expressed her great fear to do so, feeling that she might die in the dentist's chair. I treated her medicinally and advised the tooth brush, but without any improvement. She then visited one of our older cardiologists, without result, and returned a few weeks later to my office. I advised her to try the treatments. The result was marvelous. She started very gradually to feel better, stronger, and towards the close of the treatments she was able to go out shopping and carry the bundles herself. The heart's rate gradually decreased to 85 and became steady, the extrasystoles became less frequent and eventually entirely disappeared. She visited me recently. It is nearly two years since she

[2]Honey is sugar in its best form for the cardiac, though cane sugar, but not beet sugar, may take its place. Beet sugar according to Goulston's (6) experience seems not to possess any nutritional value for the heart muscle while cane sugar does so specifically. Why it is so he is unable to say. He cites a curious fact confirming the great difference in the nutritive value of these sugars told to him by practical bee keepers that the syrup made for feeding bees in winter must be made with cane sugar, for if it is made with beet sugar, the bees deteriorate, many contract diseases and die.

[3]That is during the course of quartz treatments the patient is instructed to ingest several times a day moderate doses of calcium salts, in any form, iron in small doses, and honey, diluted in milk or water, as I had the opportunity to observe that the use of either of them alone, i.e., the quartz light or medication (the latter stands for calcium salts, iron and sugar) is of less advantage than the use of both conjointly, for my patients were automatically divided into three classes. Some, who did not care for any medication, received radiation only. There was another class who could not afford to take treatments and received medication only. A great number however, constituted a third class where both medication and ultra-violet radiation were utilized. The best results were obtained with this class.

[4]That is, "such a slight reaction that only a delicate pink can be detected on the treated area which is not followed by easily visible exfoliation of epidermis" (7).

[5]That is, "one where the reddening of the skin is apparent at a glance after the reaction has appeared, and is followed by a granular exfoliation of the epidermis" (7).

was treated. Her heart rate is normal. There are no extrasystoles. She feels well and is self confident in her improvement, for she goes out alone which she never dared to do before, fearing to drop dead in the street, as a doctor said that this could happen to her. Her teeth are still in the same condition.

Case II.—Miss M., aged twenty-five. She had had scarlet fever and nephritis as a child. Two years ago acute rheumatic arthritis developed, involving nearly all joints one after another which became swollen, red and painful, with very painful subcutaneous fibroid nodules on tendons about the fingers, hands and wrists. I was the last physician treating her condition from which she apparently perfectly recovered after two months of illness. During the illness the heart did not show any suspectable sign or symptom. A few months later she came to me complaining of discomfort about the chest accompanied by dyspnea especially on walking upstairs, dizziness, tiredness as soon as she walked a few blocks which she never experienced before. Physical examination revealed the presence of a systolic murmur, rather harsh in character transmitted upward along the sternum. There was apparently no enlargement of the heart, P^2 was slightly accentuated. It is important to remember that some diseases, such as rheumatism, nearly always do damage, though not immediately noticeable. Setting in, insidiously, like a thief, their mischief eventually comes up to the surface (Aschoff). In view of her comparatively recent rheumatic condition, it was plain that the patient had a valvular lesion of recent development, or the lesion was in the process of development. The treatments were started immediately. There was a gradual improvement in her subjective symptoms, and after a sufficient number of exposures the murmur became barely perceptible. She visits me occasionally, feels very well and walks upstairs without any discomfort. Many cases of interest could be cited, if space would permit.

I am not the only worker in this field, i. e., attempting to improve or cure cardiac conditions by the use of quartz light, for Bach (11) of Germany lays claim to even greater results than I do, as seen from his following words: "The author—Bach—has obtained without exception not only passing but permanent and indeed striking improvements in a considerable number of cases of heart trouble with failure of compensation, insufficiency of the mitral valve, dilatation," etc., but the work was started by me independently.

Case III.—This is a report of my first case. In March, 1923, a girl suffering from acne indurata presented herself for treatment. Routine examination disclosed the presence of a functional systolic murmur. The patient also complained of some subjective symptoms concerning her heart. The modus operandi of the treatments was much the same as that outlined above. After a considerable number of treatments the patient's heart was incidentally reexamined. The murmur could not be detected. The patient also stated that she felt on the whole much better than she ever did before.

As one who has been doing cardiac work since 1920, I decided to elaborate upon the treatments and apply them in various cardiac conditions, and the story of my experience is given above.

COMMENT

The clinical results obtained by the treatments are based upon their nutritional and detoxifying effects. The former was touched upon above. Concerning the latter the quartz light is known for its detoxifying influence by increasing body elimination, while one of the important properties of calcium salts, "diluted in the body fluids they are a detriment to toxin" (12).

SUMMARY

Physiologically the heart for its daily work needs minerals (chiefly calcium salts) and sugar. The cardiac patient due to disturbance of metabolism of calcium, lost these nutritive salts which must be replaced in order to improve or cure his diseased condition. The replacement of calcium simply by appropriate diet and administration of calcium salts may not be of use until his calcium metabolism is corrected. For the latter the ultraviolet rays are theoretically and practically of recognized value. The employment of calcium salts, iron and sugar conjointly with ultraviolet rays seems to be of greater advantage than either of them, i. e., the medication or the rays, used alone.

Cardiac conditions treated by the author with encouraging results: Myocardial affections with continuously increased heart's rate, extrasystoles, recently developed valvular insufficiencies due to rheumatism, and functional disturbances of the heart. The clinical results obtained by the treatments are based upon their nutritional and detoxifying effect.

340 East Seventeenth Street.

Noninfective Arthritis in Women.—E. P. Cumberbatch and C. A. Robinson (*British Medical Journal,* April 3, 1926) have observed a series of cases of arthritis in women in which it seemed clear that no infection existed. These cases were either in young women in whom the onset of the arthritis coincided with the establishment of menstruation, or in women at or about the age of the menopause. It seems that in some of these cases of arthritis in which no focus of infection can be found are due to absence or deficiency of hormones of the ovary or other pelvic organ. These are amenable to treatment by diathermy applied to the pelvic organs. Heating of these organs by diathermy has resulted in subsidence of the inflammation of the joints and complete functional restoration, unless such new bone formation or other organic changes have taken place as to render restoration of function impossible.

The New Building of the New York Academy of Medicine

The opening of the new building of the New York Academy of Medicine on Fifth Avenue and 103d Street was celebrated by a dinner in honor of the newly elected honorary fellows at the Waldorf-Astoria Hotel on the evening of November 17th, formal opening exercises at the new building on the next afternoon, and the presentation of the newly elected honorary fellows, followed by the Carpenter lecture by Professor Pupin in the evening. The library was opened for consultation on the following morning, November 18th, having been closed for the preceding ten days while the books were being moved from the old building in Forty-third Street. A detailed description of the new building, the addresses delivered at the dinner and the opening exercises appear in the pages which follow.

THE DINNER

The banquet hall of the Waldorf-Astoria Hotel was completely filled by the guests, when after the elaborate dinner had been disposed of Dr. George D. Stewart introduced as the first speaker Dr. Harvey W. Cushing, of Boston, surgeon in chief of the Peter Bent Brigham Hospital. Dr. Cushing spoke of the library as a factor in the medical field, giving a brief outline of the history of the Boston Medical Library Association, which was founded over a hundred years ago. Dr. Stewart next introduced Hon. James J. Walker, Mayor of the City of New York, who said, among other things, that when it became necessary for him to appoint a Commissioner of Health he consulted the Academy of Medicine. The Academy had no candidate to offer but did aid him materially by endorsing two of the several names under consideration. One of the two thus endorsed had been appointed and, he was happy to say, had made a most efficient officer. Mayor Walker said

that he owed this country a debt that he could never hope to repay for the opportunities which it had offered to his father when he landed here a poor immigrant fifty years ago. He felt that he was under special obligations to do all that lay in his power to improve that cosmopolitan section of the city in which he had been born and reared; where bits of China, of Russia, of Italy, of Roumania, and of Ireland were crowded together into what was referred to as "the slums," a name and a condition which he hated and which he was doing his best to wipe off the map of the city. He was grateful to the Academy for its aid and knew he could continue to count upon it for the future in his efforts, through the health department, to better the sanitary conditions and to improve the health of the citizens of the greatest city in the world.

Dr. George E. de Schweinitz, professor of ophthalmology, University of Pennsylvania, spoke as a representative of the College of Physicians of Philadelphia. Dr. William Sidney Thayer, professor emeritus, Johns Hopkins University, pictured the emotions which would be felt by Laennec, the anniversary of whose birth happened to coincide with this celebration, if it were possible for his spirit to take part in these festivities. Sir Ewan John McLean, professor of obstetrics, University of Wales, Cardiff, spoke briefly as the representative of the British Medical Association.

FORMAL OPENING

The formal opening of the new building on the afternoon of November 18th began with an invocation by the Reverend Henry Sloane Coffin. The president of the Academy, Dr. Samuel A. Brown, presented a brief address on The Services of the Academy in Medical Progress, and Dr. Arthur B. Duel, chairman of the building committee, reviewed the building of the Academy. An informal reception followed, tea being served and the guests invited to inspect the building.

Among the visitors present at the afternoon reception and inspection was an interesting group of medical librarians, including Charles Percy Fischer, librarian of the College of Physicians of Philadelphia; Charles Frankenburg, librarian of the Kings County (N. Y.) Medical Society; Miss L. M. D. Trask, librarian of the Rockefeller Institute of Medical Research; Miss M. C. Noyes, librarian, and Miss Louise Kay, assistant librarian of the Medico-Chirurgical Faculty of Baltimore.

In the evening honorary fellowships were conferred on the following men, the citations being read by Dr. Linsley Williams: Robert Barany, Upsala; Edward William Archibald, Montreal; Charles James Martin, London; Sir George Newman, London; Sir Charles Sherrington, Oxford; Henry Head, London; Marin T. Tuffier, Paris; George F. I. Widal, Paris; Josef Jadassohn, Breslau; Friedrich von Müller, Munich; Friedrich Neufeld, Berlin; Vittorio Putti, Bologna; Carlos Chagas, Rio de Janeiro; John Jacob Abel, Baltimore; Frank Billings, Chicago; Harvey W. Cushing, Boston; George E. de Schweinitz, Philadelphia; George Dock, Pasadena; John M. T. Finney, Baltimore; Chevalier Jackson, Philadelphia; Theobald Smith, Princeton, and William Sydney Thayer, Baltimore. Of these only Dr. Cushing, Dr. Thayer, and Dr. de Schweinitz were present.

The Value of Books to the Medical Profession

HARVEY W. CUSHING, M.D.
Boston, Mass.

We come here, ladies and gentlemen, on this auspicious occasion, so far as I am aware, to talk about books and a library, and what is more, about the doctors' book and the doctors' library. The history of our great community libraries containing medical books is a most unusual and interesting one.

These great assemblages of books have usually begun with an individual with bookish tendencies; he gathers some people about him in a book and journal club. Books accumulate and there is no suitable place to put them. The public libraries are tried but they are poor caretakers for a strictly professional foundling, and so the doctors are thrown on their own resources, and this is a very good thing for the doctor. The profession cannot long play the cuckoo in the matter of its books. It must build its own nest, must care for its own books. A book conscience thereby developed serves as the best possible measure of the status of the profession. As the calorimeter tells the activity of the patient's metabolism, so may you determine the plus or minus activity of the profession anywhere by the character and condition of its community library. And none less well may you gauge by the same measure the quality of a medical school, of a hospital, of a laboratory, of the individual doctor himself.

There is one peculiar thing about books insufficiently emphasized. They are bibliotrophic, one attracting another, for books don't quarrel—only their authors. House them properly and other books will instinctively come to roost, and given a good working library, rich in its books of reference, its usefulness depends upon the encouragement and convenience it offers to the reader and on the infectious enthusiasm and spirit of its working staff. The testy librarian of tradition, miserly of his treasures, nearsightedly buried in his latest acquisition, impatient of interruptions, is an extinct species, and if such persons ever really existed outside the pages of fiction it would be charitable to us to ascribe their traits to the absentmindedness that a most exacting task is prone to engender.

You have doubtless heard how late one afternoon the college librarian started home with a friend, and finding that it was raining returned to the library for his umbrella. As he did not reappear he was sought for and found absently looking for the object under "U" in the catalogue.

DR. JOHN W. FRANCIS
President, 1848, 1855

To inoculate a doctor with the library habit he must be caught young. You must set a trap for him so bated he will walk into it unawares. There is no use to counsel him to read. Books must be put in his way so that he will stumble over them and make his own discoveries.

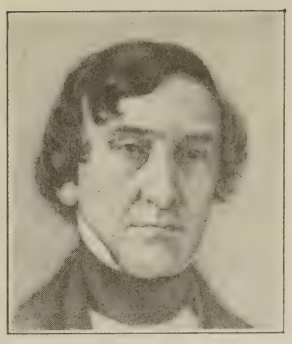
William James once told how as a child he discovered a huge book one rainy afternoon in the garret of his father's house. He read it with absorbed interest till called to his supper, then told his mother he had found a most wonderful book full of battles and killing of people. It was called "The Holly Bibble."

It is someone's business in every medical school to teach laboratory methods to students, but no one's business to teach them how to use medical literature which will be infinitely more useful to them than experience with smoked paper and Ludwig's drum. Short talks on the use of such a library as yours might well be made obligatory, sectional exercise for medical students. Such exercises, I am aware, and methods of looking up subjects, or the use of the great indices sometimes meet with discouragement, as when the student requests a copy of "Ibid." as being just the work he is looking for.

No, there is only one thing to do with the young man in these days of the movie and jazz and the flivver; place both books and cigarettes in his way and caution him to beware of them as dangerous. He will certainly take to one, perhaps to both. This may, after all, be the right track, to warn young people against books as a bad habit, or at least against book collecting, for one may become enslaved and soon so enveloped by books they are in the front hall and in the dining room till you never can find the volume you want and you are sure your wife or the children must have taken them when they borrowed your paste pot.

This, I take it, is what has happened to your New York Academy of Medicine and explains this meeting. You had become so swamped with books in your original quarters that the original volumes could not be found when called for. In fact, beware of books. Some biologist has stated that if nature could take her course unimpeded the world would become populated with elephants wallowing about knee deep in a seething mass of mice. This man knew nothing about books. As a species they are imperishable. Against their multiplication nature has no chance whatsoever. The time will come when every tree has been felled for paper, every calf for leather and the few long haired and ill nourished people left in the world will be making card indices of the volumes which have filled every available cranny in which they can be stored.

Laws will have to be passed against their importation; only a quota of French, German, Italian and Polish (especially Polish) books will be admitted each year, for should you happen to leave a pair of foreign books long on a shelf in the state known as their original wrappers, they breed with amazing rapidity. Then, too, they have their diseases and are troubled like too many children—they have worms, they wear out their clothing, they break their backs, they dislocate their joints, they require the constant care of a bibliotherapeutist.



DR. FRANCIS UPTON JOHNSTON
Vice-President, 1847

But there is no use telling you to beware of books when you have already burned your bridges. Books will like the looks of your new building and come in such swarms, you will be driven out and into a new building in another generation. A library which does not grow is the corpus inanimi—the better it is, the faster it grows.

We in Boston made the usual small beginning more than a century ago, the books of a doctor's club in the house of an individual doctor. Then they moved to an apothecary shop, then to the medical school, thence to a public library, thence to a succession of supposed permanent homes. The first was the former dwelling of Dr. Samuel Greeley Howe (who happened to marry "The Battle Hymn of the Republic," which served to obscure Samuel in favor of Julia) thence to a larger home, then to a beautiful Academy building where now there are so many books there is scarce standing room for the librarian and his staff.

Fortunate as the older communities like Philadelphia, Boston and New York may be in their present magnificent collections, there are always more books to buy and one cannot afford to wait for donations. The more precious classics of medicine, the number of which is limited, grow more and more rare, more and more expensive for the competition is great. New schools are being founded that know the value of books. It is rumored that Tulane is buying, also Rochester, Cleveland, Detroit, Pittsburgh and the new Duke University plans to have a great library for its medical department. So even a school of undergraduates may enter into competition with you for books.

At the Johns Hopkins Library, they have drawn plans for a building with a potential stack room for nigh half a million volumes and appointed a one time New Yorker whose name spells success for whatever he attempts to fill another chair as professor of the history of medicine. Such a post for such a man in such a place indicates progress in medical science, merely building on a knowledge of the past of which libraries are the storehouse. The tendency of our recent times has been to lavish gifts on our laboratories and neglect our libraries, but medicine needs both if we are to uphold our vaunted reputation of being a scholarly profession.

I bring to you, Mr. President, from the Boston Medical Library Association our greetings and not only our greetings but congratulations on the transfer of your precious collection of books to its new quarters.

The College of Physicians of Philadelphia

GEORGE E. DE SCHWEINITZ, M.D.
Philadelphia

It is a real privilege to be here tonight and to hold in happy anticipation an invitation to take part in the ceremonies of tomorrow which shall signalize a notable achievement in the fair field of medical endeavor.

It is an honor to represent the College of Physicians of Philadelphia, for I assume that this pleasant task and highly appreciated duty constitute my credentials, and to bring to you, Mr. President and Members of the Academy of Medicine of New York, the hearty felicitations of the collegiate body which I have named on the consummation of your labors and the fulfilment of your cherished desires.

The Academy of Medicine of New York and the College of Physicians of Philadelphia, separated in distance by about a hundred miles, are unseparated in their cooperative effort to maintain the dignity of literary intercourse and acquirements, and to enhance the value of medical and surgical effort.

"Like mighty partners, equally they raise
Yet neither envious of the other's praise."

I have denominated membership in the College of Physicians as my credential, and hence it is not out of place, following a suggestion of your secretary, to say a few words which shall serve to introduce the Philadelphia institution to the New York Academy of Medicine, even though I know full well that we are acquainted, and that on many pleasant occasions representatives of our respective memberships have exchanged pulpits (let us hope to mutual satisfaction), and that therefore I come not altogether as a stranger, not merely as a colleague, but, quite happily, as a warm and admiring friend.

The erection of a College of Physicians in Philadelphia was, in 1767, suggested to Thomas Penn by John Morgan, but his proposals were rejected and a charter was refused. Subsequently several physicians, who later became Fellows of the College, after their graduation from the School of Medicine of the University of Pennsylvania (then called the College of Philadelphia) went to Edinburgh and London to enhance their medical education, and, struck with the success and value of societies in those cities, on their return debated the need of similar efforts in the new country, and Samuel Powell Griffith expressly states, writing in 1783, that an American College of Physicians constituted an urgent need. Similar ideas were recorded in letters which passed between the physicians to whom I have referred and friends they had made in England and Scotland. Therefore several forces were active in the foundation of the College in Philadelphia, and the Royal College of Physicians of London became its prototype.

Although instituted in 1786, when an election of officers took place, the first meeting after full organization did not occur until January 2, 1787, and this day, by common consent, is regarded as its official birthday, and in less than two months from today its 140th anniversary will be celebrated.

Those present at this first meeting, namely, John Redman, president; John Jones, vice-president; Gerardus Clarkson, treasurer; James Hutchinson, secretary; and William Shippen, Jr., Benjamin Rush, John Morgan and Adam Kuhn, censors, signed the constitution, and the device for the seal was adopted which reads *"Non sibi sed toti."*

In the quaint language of this Constitution, it is stated that "the objects of this College are, to advance the Science of Medicine, and thereby to lessen Human Misery, by investigating the diseases and remedies which are peculiar to our Country, by observing the effects of different seasons, climates, and situations upon the Human body, by recording the changes that are produced in diseases by the progress of Agriculture, Arts, Population, and Manners, by searching for Medicines in our Woods, Waters, and the bowels of the Earth, by enlarging our avenues to knowledge from the discoveries and publications of foreign Countries; by appointing stated times for Literary intercourse and communications, and by cultivating order and uniformity in the practice of Physick."

The Fellows of the College were selected from "persons of merit in the profession of medicine"; by direction "good moral conduct and decent deportment" became a *sine qua non* of eligibility.

One month after the College was founded, Benjaman Rush wrote: "By assuming the name of a College, we shall first be able to introduce order and dignity into the practice of physic, by establishing incentives and rewards of character. . . . Our meetings will serve to correct or to improve our conduct. And if we are as chaste as we should be, in the admission of members, a fellowship in our College will become in time not only the sign of ability, but an introduction to business and reputation in physic."

Even as Benjamin of old settled his tribe in the fertile valley between Ephraim and Judah, so this canny Benjamin of a later day realizing, again to quote, that "an Fellowship in the College would mean an introduction to business and reputation in physic," we had faith that the area between the Schuylkill and the Delaware would prove to be "a fertile one," and his faith has been justified.

For almost a century and a half the Fellows of the College have followed the line of conduct laid down by the founders, and have striven to maintain a proper relation to the ethics of the profession, to assume a guardianship over the health, safety and morals of the community, and to lend their aid to medical effort, medical achievement, medical research and medical literary advancement.

True to the tradition of all physicians who approach their tasks with rightness of heart, force of character and straight thinking the records of the Fellows in peace, war and pestilence are clean.

When the days from 1793-1798 were evil, and in Philadelphia yellow fever took its heavy toll of victims, they exhibited, as all physicians always have done in all emergencies, unselfish devotion to duty regardless of personal danger, even though their con-

ferences were not always free from disagreement as to the etiology of this plague, which they disputed, as Hacket would say, with an acrimony of voice and gesture. The names of two of the founders of the College find place on "the illustrious head roll of medical martyrs."

But it is not of medical effort in war and disaster that I should speak, for we are content to know that physicians in all lands have not failed to serve their governments in times of dire distress, and serving with fine fidelity, have written noble chapters into the war histories and sanitary records of their respective countries.

The prime object of a College of Physicians or an Academy of Medicine is to enlarge our avenues to knowledge from the discoveries and publications, not only of the countries in which they exist, but from those of foreign lands—hence the need of establishing libraries. The library in the College of Physicians in Philadelphia began in 1788 by a donation of twenty-four volumes from John Morgan. Slowly at first, but in later years swiftly, it has developed, and today its bookstacks and shelves contain 149,739 bound volumes, 26,797 theses and dissertations, and 163,786 pamphlets, at present being sorted according to subjects preparatory to binding. Among these volumes are many rare and valuable books, and of incunabula we possess 371 titles and 255 volumes, of which 240 photostat copies have been made. In the journal room the current medical literature of the day in all modern languages is well displayed and of easy access, and at this time the total number of such periodical publications received is 1,203.

The Library of the New York Academy of Medicine, like the one to which reference has been made, is also a splendid storehouse of the gathered thoughts and the scientific records of medical men. I extend to you congratulations from the College I have the honor to represent on this fine achievement. Once more we are, indeed, "mighty partners," each glad of the other's success, neither envious of the other's praise.

These libraries, and I do not forget those of established and mounting reputation in other cities of the country, constitute interpretations of our steadfast endeavor to elevate the standard of medical achievement and enhance the value of literary effort. They have gained and maintained their allotted order of precedence among the best of the great medical book collections of the world. Deeply impressed as I am, and as all of us are, by the importance of such achievements, I am equally impressed by the necessity of cooperation, the necessity of working for the profession to which we have the honor to belong, in "perfect sympathy and uncontending equity."

Membership in the New York Academy of Medicine, and I trust also in the College of Physicians of Philadelphia, constitutes a patent of nobility, and carries with it a compelling responsibility—the responsibility which resides in organized medical effort with relation to community service in the widest acceptation of that term. Of course I know how great the endeavors along these lines have been and are, but I know of no reason why they should be not greater, more effective, and more satisfactorily carried on, especially as they are concerned with proper publicity through the channels best equipped to reach the largest audience. I hope the day is not far distant when on some occasion there may be a combined meeting of the New York Academy of Medicine and the College of Physicians of Philadelphia, and the whole matter discussed and rearranged.

And now I crave permission to join with the members of the Academy of Medicine of New York in saluting your guests from afar, and in avowal of our debt to them and to the medical and scientific achievements of the countries they represent—a debt we gladly acknowledge, a debt we cheerfully own. I am sure there is no member of our fraternity here tonight who, when writing up the credit page of the ledger of his life, does not smile happily at many entries he is enabled to make because of stimulation and instruction he has received in the laboratories and clinics across the seas.

Importance of the Library in Medical Practice

WILLIAM S. THAYER, M.D.
Baltimore, Md.

It is interesting to reflect that when we meet tomorrow at the beautiful new building of the Academy, the point of reunion for all students of medicine in this great community, 'twill be about the Library that we gather. The library—the book—is still the common point about which students collect today, as, centuries ago, readers met about the old tomes chained to their shelves.

In the dark ages of blind reverence for authority, the manuscript, the book, the great compilation gathered about the aphorisms of an old master whose word was as revealed, was the foundation of all knowledge. The old master had been generally a keen observer and a wise man; the scribe too often was his servile worshipper, spinning a web of more or less valuable discussion about the kernel of the annals of the seer. Man who has always been a slave to the word, bowed down before the book. The tyranny of words has aways been the most dangerous of human powers.

But there were men who dared to look for themselves; who dared to seek and who found; who dared to knock and to whom it was opened. These men, who had burst the confining bonds of the tyranny of words, to whom the search for truth was above the worship of authority, consigned to the written page their observations, their experience, their perceptions, their deductions, their opinions, sometimes in cryptic phrase, sometimes openly; and sometimes, as Michael Servetus, they gave their lives in payment. First the anatomists and then, as Allbutt has so well pointed out, the humble surgeon in the days when

"sacerdotal, scholastic and military convention" had excommunicated surgery and made that false and pernicious schism in medicine in its broader sense which exists to the present day. The anatomist and the surgeon led the way, in times when the physician was indulging in vain dialectics as to the arm from which one should bleed, and were entering on what Huchard calls "the antimonial war of a century." Precious milestones, these works, in the annals of medicine, preserved for us all in libraries such as yours.

The physiologist and the student of pathology in its full sense followed, and with the improvement of the art of printing, medical literature, no longer restricted to dissertations on the canons of the master, became a record of the experience, the achievements, the constatations, if one may use the word, the hypotheses of the observer and the experimenter.

The birth one might almost say of the art of diagnosis of internal disease, dating from the time of Morgagni and Avenbrugger and Laennec, placed the physician on his own feet, and began to wean him from his servile worship of the assertion of another. On the other hand, rapidly accumulating contributions to medical science and art printed in an increasing number of books and periodicals in all countries and in all languages, rendered the library more and more necessary to student and practitioner.

Medical literature was no longer the record of authority; it became the record of achievement. The contributions of the last fifty years with the birth of an art of therapy based on scientific foundations are recorded in a literature increasingly voluminous.

But in this old world there are still vestiges of virgin forest. From the prostrate trunks of stately trees has sprung, alas, a literature which is as a "pestilence that walketh in darkness"—a "destruction that wasteth by noonday."

Have you ever happened on river or lake, to meet with the birth of a generation of "Mayflies." You are gazing peacefully at a lovely sunset, and of a sudden, the air is full of flying things—light, thin, long, squirming, green, almost translucent bodies with large transparent spotted wings. They come in clouds. In a moment you are covered. They are in your eyes, your ears, your nose, crawling down your neck and up your sleeves. You rush for cover, and as you go you tread on a crackling mass, and slip on the slimy bodies of myriads crushed under your feet as they carpet the deck. Once within, you may open neither door nor window, through which light no longer comes. Without, everything is covered and hidden by layers an inch or more thick. Ephemeridæ, they are sluggish in the morning, shriveled and dead by another night, but in their lifetime they have shut the light from your eyes and hidden all that you would see, while the slime from their bodies, crushed as you pass, tangles your feet and hinders your progress.

Even so from the trunks of the felled trees of the virgin forest has arisen a substance by courtesy or convention called "paper"—a crying insult to the paper of the past! From this burlesque on paper there has burst upon us a cloud of "literature," not only general but medical, which obscures the sky. As by a generation of Mayflies, we are submerged by medical ephemeridæ. Advertisements of every imaginable sort, periodicals, columns in the daily press, carefully "written down" for the intelligence of a child. Books written to record the experiments, studies or the achievements of the author? Oh! no. Books written on time, at the request of a publisher—compilations, in great part, and too often of little value. For medical literature today is largely the literature of the publisher.

Smothered and blinded by this plague of ephemeridæ, 'tis to the library again that we turn. As the sailor sweeps the deck, so the devoted librarian sorts and classifies and catalogues or sweeps away and burns this incubus of literature, so that we may more readily find the jewels buried beneath the ephemeral cloud.

That this great and growing library should now at last have a home fully worthy its present excellence and its future promise is of happy omen for the profession and public of this city and of the country at large.

'Tis not uninteresting that this year, the year of the opening of your new building, is a medical anniversary of some importance. 'Tis the centenary of the death of Laennec, and of the birth of the second great edition of his book in which is set forth for the first time the real basis of pulmonary diagnosis.

A charming figure he must have been. The little, spirited, spiritual man, the architype of the Celt, with his oval face, his large expressive eyes, the long humorous upper lip. Scholar and classicist, who at eleven had translated the first Georgic of Virgil into good French meter; poet, who at the same age was writing fables in excellent verse; lover of nature and of music; profound, devoted student with a deep reverence for those who had gone before; whose inaugural thesis was on the doctrine of Hippocrates, whose works he had read and pondered in the original Greek. Anatomist who at the very outset of his career had described the subdeltoid bursa and the capsule of the liver. Pathologist, whose description of peritonitis as a pathological and clinical entity, published in the earliest years of his medical life, is a classic; whose anatomical and clinical descriptions have never been surpassed. Inventor of the stethoscope. Author of *Ausculation médiate* in which is set forth a method of clinical procedure which is a model for all time; which contains descriptions—in good part original—especially those of bronchiectasis and emphysema—of pathological changes in the lungs and of methods of clinical recognition of such changes which are the very basis of modern clinical medicine. Vigorous defender of his ideas, and spirited, sometimes bitter opponent of his contradictors. Brilliant, successful, wise practitioner and teacher, devout withal, and one of a group presented to the Pope, which was greeted by the memorable exclamation: *"Medicus pius—res miranda!"* (a pious doctor, marvelous object!). Dead at forty-four of that disease to which he had given so much of his life. The father of modern diagnosis.

Fancy for a moment that the angel Ithuriel, disturbed by the reports of the press and Sinclair Lewis' novels, were to dispatch Laennec to inspect the medical circles of New York, as he sent Barbouc some years ago to Persepolis. Fancy the delight of the little master at the advances in our knowledge of dis-

DR. VALENTINE MOTT
President, 1849, 1857

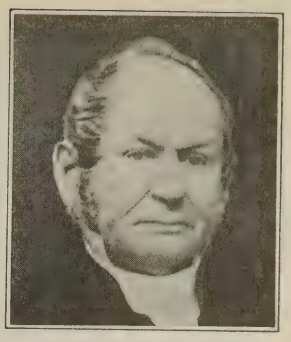
ease, at that which bacteriological and serological studies have brought; at the applications of chemistry and physics to the medical sciences; at the possibilities of modern diagnosis; at the multitude of instruments of precision, the clinical thermometer, the ophthalmoscope, the laryngoscope, the use of the electric light in endoscopy in all its forms, the sphygmomanometer, the x ray; at the growth of a therapy resting on a scientific basis; at the schools and libraries and hospitals such as you would show him today.

But fancy for a moment his surprise, when, on entering a hospital ward—the little master in his swallowtail and choker, his big stethoscope in its green leather case in his coattail pocket—fancy his surprise on entering the ward and finding himself face to face with a comely nurse with jaunty cap and bobbed hair, and plucked eyebrows, and slightly hectic cheeks, and pale nose, and curiously cyanotic lips, and shortish skirts; or on meeting in the corridors those visions of beauty with shorter skirts and bobbed hair whose very presence is a social service! Fancy what his feelings would have been! But no, rather let us refrain! There may be reporters in the room. I fear that he might suspect with the Reverend Increase Mather, that the devil appearing as an angelical apparition might lurk behind these alluring visions! He would have to learn, but he would learn in time, that they *are* "angels of light" after all.

And then fancy his surprise at the language employed at the bedside—Laennec who always dictated his opinions and diagnoses to his students in Latin, *"pour des raisons faciles à sentir,"* as he said. Latin! Gone in one short century! Latin—for so many hundred years the language of scholars. "What on earth," he would say, "is the sense of wasting years in the acquisition of a few barbarous modern languages when in Latin all scholars may meet?" "That new word 'standardization' which rather offends my ear," he would reflect, "seems to be a sort of semi-religious ideal of this strange new generation which is feverishly seeking the shorter way. But the one standard which has endured through more than fifty generations, Latin the language of learning and of the church, this one standard they have thrown away. 'Tis passing strange!" But when some bright-eyed enthusiast told him of "Esperanto," he would understand. He would open his mouth, nod his head, tap his forehead and whisper to himself: "Ah mad!—all mad!"

And when he saw men looking at x ray plates before they examined the chest, making pulmonary diagnoses, perhaps, from a plate alone—or blindly accepting the opinion expressed by the radiologist without so much as seeing the plates—when he saw this he would cry aloud: "But these are shadows that you are chasing! Listen, touch, smell, look! Look at your patient before you turn to shadows. From the shadow you may learn much, but would you interpret life and reality which is before you from shadows alone?"

He would marvel at the new therapy resting on scientific foundations. But when he, who was so careful and considerate of his patient, saw the advertisements of our wholesale chemists, and the manner in which their products are used by some of our colleagues on the mere basis of the conscienceless and preposterous statements contained in this literature; when he saw the amazingly reckless manner, the levity, one might almost say, with which poisoning substances of all sorts, notably mercurial and arsenical compounds, are introduced into the circulation of the patient, he might ask himself, what had become of the careful methods of clinical and pathological control which he had helped to initiate. He might indeed ask himself if the indiscriminate bleeding of his own day were not perhaps less harmful and equally intelligent.



DR. THOMAS COCK
Vice-President, 1847
President, 1852

Fancy his satisfaction at the coöperation shown in the study of diagnostic and therapeutic problems in our better hospitals and clinics; but fancy his surprise and uneasiness at the exaggerated subdivision of the work in some clinics and some institutions, and at the frank and open speculation on the supposed fortunes of their patients by some physicians and surgeons.

And then when he read *Arrowsmith* and talked with the misanthropic individuals who are always with us ready to gloat over the iniquities of this world, might he not well have some anxiety as to the future of medicine? But when he met the leaders of medicine in New York today, when he went out into the rural medical societies and associated with the country doctor; when he met and communed with such men as are in this hall tonight, he would surely realize that the doctors of today are in the vast majority of instances a fine, highminded set of fellows, trying to do their best, associating and working together for the common good, far more intimately and far more harmoniously than was ever done in his day.

And when his visit was done and his report was due he would have made by the best founder in the city, a beautiful model of the new quarters of the Academy of Medicine, "composed of all metals, earths, and stones, the most precious and the most vile." He would lay it at the feet of Ithuriel, and he would say: "Your serene highness" for he was a courtier, and even angels are susceptible to adulation, "Your serene highness, I have visited New York. I have found men and women, physicians and laymen much as they were in my own day; as credulous, as prejudiced, as suspicious, as covetous as we were. They have the same old faults, the same old passions, the same old prejudices. They live in a country which boasts much of its freedom, and sometimes they seem to me hardly so tolerant as we were a hundred years ago. But collectively they are re-

sponsible for this beautiful thing, and all that it represents, infinitely more beautiful and beneficent than anything that existed or could have existed—than anything we could have dreamed of in my day. Shall we break this lovely thing, because all that is in it is not gold and diamonds? Shall we condemn all this beauty and all this progress in the science and art of medicine, all this spirit of coöperation among medical men, because after all it is the work of men and women with all their human frailties. In your own words, *'Si tout n'est pas bien, tout est passable'*, (if all is not well, all is passable) and so much more so than in my day! May it please your highness, if I might be allowed to suggest such a thing, may I dare to hope that in another century, your serene highness may consider the possibility of sending me back again? And may I be justified in expressing the hope that your highness will assign me to the New York Academy of Medicine? And that if it be not too much trouble, your highness might arrange to send George Stewart with me to preside at the dinner?"

The Building of the Academy

ARTHUR B. DUEL, M.D.
Chairman Building Committee

There is no more striking human characteristic than the desire to own and maintain a home. The American has been possessed with this same desire in the same way as has existed in other civilization. Man desires a home primarily for shelter for himself, his wife and his children. This is his primary desire, but relatively few of them appreciate the mental, moral and spiritual features that rarely exist outside of the home. This home instinct has been sadly injured by the enormous growth of our urban interests, disrupted by the facility of modern communication and made increasingly difficult by the extravagance and congestion of our city life. One hundred years ago in this country, the home was practically the only meeting place for social intercourse, and there the members of the family heard discussed by their elders, the various problems of the day—politics, religion, education and all matters pertaining to community life.

It is therefore natural that groups of individuals are prompted to seek a home or meeting place, in the present day, when homes are no longer available, except in rare instances, for permitting free discussions and providing facilities for social intercourse.

Eighty years ago a group of physicians living in New York City were strongly urged of the need of bringing together from time to time the leaders in the medical profession in the fields of practice, teaching and research, for the purpose of taking counsel with each other; and for advancing the practice and art of medicine; and for the promotion of public health. The leader of this movement was Dr. John W. Francis, a dominant figure in those days, whose efforts were successful in bringing about the organization of the New York Academy of Medicine. The majority of the doctors who were interested in the formation of the Academy were active members of the Society for the Widows and Orphans of Medical Men, which organization still exists and has offices in the present building of the Academy.

The search for a home began immediately, though it could only serve the purpose of providing temporary housing for the first born child, namely, the promotion of the art and practice of medicine by the holding of meetings and conferences. These meetings were held, first at the Lyceum of Natural History, then at the Convention Hall in Wooster Street, later at New York University, and since then at the last temporary quarters at the College of Physicians and Surgeons. The search for a permanent home continued, and it was finally possible for the fellows of the Academy and their friends to secure what we would now consider old fashioned—a high-stoop, brownstone home at 12 West Thirty-first Street, which was opened in 1875. The desire of the fellows to render more service to the profession, soon prompted them to organize a library and to subscribe to the current medical journals, so that the fellows of the Academy might keep abreast of the progress of medical science. The leader of this movement was Dr. Samuel Smith Purple, who made the first contribution to the library as soon as the new home of the Academy was opened on Thirty-first Street. This was the second child of the Academy whose growth and development have been prodigious. The Academy, having increased in numbers and the meetings becoming steadily larger, there was an urgent need for a larger room than the ordinary parlor of this old fashioned building, and as a result of the activity and generosity of Dr. Abram Du Bois, a meeting hall was built in the rear of the building, which was named after Dr. Du Bois.

Continued growth of the library and the increasing number of the Fellows made it seem imperative to have larger and more commodious quarters and as a result of continued effort, during 1887-8, a new building was constructed at 17 West Forty-third Street, which at the time seemed to fulfil all the immediate and future needs of the Academy. Its spacious meeting hall was made possible by a large gift from Mrs. Selina B. Hosack in memory of her husband, Dr. Alexander Eddy Hosack, after whom the hall was named. In appreciation of the memory of Dr. Abram Du Bois, the next largest meeting room in the new building was dedicated as Du Bois Hall.

This building proved commodious enough to permit two more children to develop lives of activity and usefulness within its walls, namely—the Public Health Committee and the Bureau of Clinical Information. The second child, however, continued to grow, and the library was soon found to be too small for future development. Not only had the stack become overcrowded but also the reading rooms, for it was the only public medical library in the City of

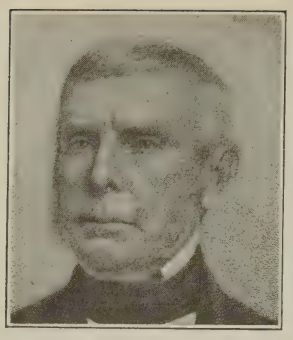
Hosack Hall, the Auditorium, on the Ground Floor

New York, until the organization of the Kings County Medical Library some years later.

As early as 1909, the library committee called attention to the urgent need for more room for books and more room for readers. During the year 1909 a scheme was proposed for the construction of a new building at Seventh Avenue and Thirty-eighth Street, and a successful effort was made to obtain additional funds. For the construction of the building, the Academy Extension Fund was created, and this increased to over $130,000 in 1911. But this was insufficient to make it possible to seriously consider the construction of the new building. In 1911 plans were drawn for alterations and additions to the existing building at Forty-third Street. A lot was purchased at 15 West Forty-third Street and an additional lot which was subsequently sold, was purchased in the rear on Forty-fourth Street. It was found that it was extremely difficult to remodel the building on account of the fact that the stack was a fixed unit and could not be enlarged without almost a complete reconstruction of the building. As funds in sufficient amount were not available, the plan was again postponed.

The continued growth of the library and the constant recommendations of the library committee for increased space, urged the trustees to reconsider the possibilities of making additions to the building at Forty-third Street and serious consideration was given to this matter in 1917. But the matter had to be left on the table on account of the war and the fact that nearly half of the Fellows of the Academy were engaged in some form of War service. The matter was taken up again in 1919 and working drawings were prepared for additions and alterations to the old building. The Fellows were never fully satisfied with this proposal as it did not permit of sufficient room for later expansion, so postponement again was the order of the day. In 1921, the picture was entirely changed when Dr. Henry S. Pritchett, the then acting president of the Carnegie Corporation, recognized the value of the services rendered by the Academy to the medical profession and thence to the public; and the possibilities of its increasing usefulness and service, and saw the need of a new building. It was not long before conferences were held with the officers of the Carnegie Corporation and the Rockefeller Foundation, and in 1922 the Carnegie Corporation voted a grant of $1,000,000 for the purpose of constructing a new building for the Academy.

During the summer of 1922, sketches were made of buildings for sites on East Fifty-seventh and Fifty-eighth Streets and also for Sixtieth Street and Park Avenue, and during the spring of 1923 the Academy engaged in an active campaign for funds to purchase a new site and an increased endowment of $206,161.64 was subscribed by 1313 Fellows of the



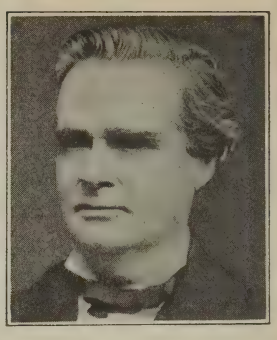
DR. JOSEPH M. SMITH
President, 1854

Academy. In addition, various friends of the Fellows contributed $324,922.78. Of this latter sum there was included a gift of $100,000 from Mr. George F. Baker, $50,000 from Mr. James B. Ford, $50,000 from Mr. Edward S. Harkness, and $50,000 from Mrs. Helen Hartley Jenkins. The trustees in this year purchased a lot at the corner of Sixtieth Street and Park Avenue, for which the sum of $750,000 was paid; and preliminary drawings were made for a building on this site, the plans for which were matured during the summer of 1923. The plans called for a building which would have cost $2,225,000, and the expense would have been large, due to the fact that on a lot 100x120 feet, it was not even practicable to build the stack anywhere but within the main building.

It should be emphasized that the limitations of growth forced the Academy to move from Thirty-first Street and the limitations of the growth of stack forced the Academy to move from Forty-third Street, and although the stack proposed at Sixtieth Street was far larger than the immediate needs of the Academy, yet it was a fixed unit and did not permit of any future expansion.

An attempt was, however, made to see what type of building could be constructed for a million dollars, and it was then thought with that sum a building could be erected which would be but a little larger than the existing building at Forty-third Street. After this attempt had been made, it was decided by the Academy that a larger building would have to be constructed on a larger lot and that elasticity must be provided for the expansion of the stack, and for future growth of the Academy's other activities. The Academy accordingly determined to sell the lot at Sixtieth Street, which was sold in 1924 for a million dollars, and the present site was purchased in the same year for $225,000, which was subsequently added to by the purchase of a lot adjoining on East 103rd Street for $17,500. The selection of a site was not easy, and it will not be necessary to consider any detail of the various considerations of sites that were made during the winter of 1924. It suffices to say that over a hundred sites were considered, many of which were inspected by the trustees, and with the inspection of several small sized, undesirable lots, none were available for a price of less than half a million dollars, with the exception of the present site. During the summer of 1924 the architects, York and Sawyer, prepared a series of schemes. The trustees determined upon the present plan, and building operations were undertaken in the spring of 1925. The cornerstone of the present building was laid on October 30, 1925, and today the building is completed.

It is now seventeen years since the first discussions were begun, which led to the culmination of our ardent desire to find a home which could be permanent and satisfactory for the needs of our family. Opportunity is now offered to inspect the building, which has been designed primarily for utility, but with the same desire that exists in every happy family, to preserve its mementoes and treasures, to embellish the home in so far as funds will permit, and to have it useful, simple, dignified and beautiful, all of which we feel have been accomplished. With full realization of the reasons why the Academy was forced to leave Thirty-first and Forty-third Streets, the building has been so constructed that the stack is a separate unit, which may be increased not only upward but also to the side, if future needs require it. The main building is also so constructed as to permit the addition of a number of stories and also the auditorium extension permits the addition of several stories above it. Who can visualize the future? We have not tried to visualize what the Academy may be or what its needs may be fifty years from now, but we have visualized in so far as is possible, and have produced a building which permits of expansion for every possible future need that can now be conceived of.



DR. J. MARION SIMS
Orator, 1857

The construction of this beautiful building could not have been possible had it not been for the enthusiasm and vision of Dr. Henry S. Pritchett; nor could it have been completed without the enthusiasm of Dr. Pritchett's successor as president of the Carnegie Corporation. Mr. Frederick P. Keppel had also been convinced of the usefulness of this growing institution and an additional gift of $550,000, making a total of $1,550,000, was contributed by the Carnegie Corporation. Nor would it have been possible to plan and develop the additional educational facilities of the Academy, included in the extending activities of the library, the Bureau of Clinical Information and the Committee on Public Health Relations without the enthusiastic support of the Rockefeller Foundation, which has promised the sum of $62,500 annually and with the capitalization of that sum in the near future of $152,000—and we here record again our everlasting gratitude to Dr. George E. Vincent and Mr. Edwin R. Embree of the Rockefeller Foundation for the interest they have taken in our work.

To the members of the library committee who served since 1909 is due no small measure of praise for their constant desire to find fireproof, permanent and commodious quarters for the library, and to the Board of Trustees and members of the Academy whose interest and patience during this long and trying period has been a striking example of service to a noble cause. I record also my gratitude and appreciation to the valued service by my colleagues on the Building Committee—and finally, I am convinced that no such building, combining such rare qualities of usefulness and beauty, could have been produced without the service of Messrs. York and Sawyer and their illustrious partner Mr. Louis Ayres, who has carried the brunt of the work and whose

vision has produced the work of this building. The construction of the building, its details and its beauty, are largely due to him, but great praise is due to Messrs. Otto and Robert J. Eidlitz, who have constructed the building under his direction. The furnishings and decorations have been the result of a combination of the artistic ability and skill of Mr. Louis Ayres and Mr. Barnet Phillips. During this process of construction, there has been no rift in the lute—all have worked together with their shoulders at the wheel for the production of a thing of beauty and a joy forever.

The Service of the Academy

SAMUEL A. BROWN, M.D.
New York
President, New York Academy of Medicine

In my contact with patients and friends, I find that the Academy of Medicine is not well understood. They say, "Oh, yes, the Academy! We presume it is connected with a medical school, or it is part of some hospital. We know that you have a library but you can't possibly need a big building for a library."

Therefore, I thought that this afternoon I would present to you some of the activities of the Academy, in order that the functions of the Academy might be better understood by many of our friends.

The Academy was organized in 1848 by a group of men who were leaders in the profession, who had in mind the betterment of the practitioner of medicine, to the end that he might render better service to the public. They devoted their energy to the advancement of medical education, to the scientific development of their members, and to all matters relating to public health.

As time went on they organized regular scientific meetings, which have been continued until the present time, and at these meetings the best minds of the country are requested and invited to present the results of their experience, so that the members of the Academy may be kept abreast with medical science.

Of course, it would not have been complete without a library. The library was started in the time of Dr. S. S. Purple, the president, when the Academy was at 12 West Thirty-first Street. It has grown from a very small beginning, until today it is the third largest medical library in the world.

The privileges of the library and the facilities of the library are not limited to the members and fellows of the Academy. They are available to medical students, to students in sciences allied to medicine, and to the public. In fact, this library occupies a position in relation to medical literature similar to that which the Public Library occupies in relation to general literature.

More recently, there has been created a Bureau of Clinical Information. This Bureau now provides information about hospitals, clinics, and postgraduate courses of various types to physicians from all parts of the country. Hundreds of physicians now come to the Academy during the year from out of town and receive advice as to the type of refreshing courses and postgraduate education which they desire to undertake. The Bureau is also able to advise foreigners in regard to courses in this country, and to advise our medical men and students of the various postgraduate courses available in Europe, thereby saving them much time in making their contacts when they go abroad.

The Academy has also devoted much time to matters of public health. This activity was graciously referred to by the Mayor at the dinner last night.

In the early days of the Academy, during the decade of 1850-1860, the Academy took a most active interest in supporting the agitation for the organization of a Board of Health, for the abatement of the evil of feeding cattle within the city limits, and other such matters. Early in this century, the Academy successfully supported a movement for the transfer of the State Quarantine Service in the Borough of New York to the Federal Government.

In 1911 the Academy organized a special committee on public health, hospitals, and budgets, and this committee has actively continued its interest in these matters as they affect the city. Through the influence of this committee, now entitled the Committee on Public Health Relations, the Academy has been successful in bringing about the abandonment of several dispensaries and other institutions no longer needed; it has been able to persuade members of institutions to change their policies in order to better them; it has published several books and pamphlets which have had an important bearing on the hospital situation in New York.

The organization of the Dispensary Development Committee was a direct result of the Committee on Public Health Relations.

Although the Academy has not taken an active part in securing new legislation, it has frequently lent its advice and influence for the modification of many laws affecting the practice, holding itself somewhat aloof from the political aspects of the situation. This may or may not be a wise thing to do.

The building of the Academy has been a meeting place for the societies of the county and the state of New York and a score or more other societies, thus bringing under one roof nearly all of the medical societies and activities of the city, especially of the Borough of Manhattan, promoting a mutual understanding, and advancing the interests of the profession.

The Academy has provided offices for the Society of Widows and Orphans of Medical Men, the New York Physicians' Mutual Aid, and many other organizations.

The Academy has also rendered a service to the

community and to the medical profession by its constant endeavor to maintain a proper standard of ethics among the members of the medical profession. Although ethics and professional courtesy are frequently misunderstood by the laity their existence is primarily for the benefit of the patient.

I have often heard this building spoken of as a beautiful monument to the profession. Personally I like to think of it as a workshop, for in years to come it will be the output of this workshop which will be carefully criticized when the justification of this large investment is to be considered.

The Men Who Made the Academy of Medicine

LINSLY R. WILLIAMS, M.D.
New York
Director of the Academy of Medicine

At the celebration of the fourth anniversary of the foundation of the Society for the Relief of Widows and Orphans of Medical Men which was held at Peletier's saloon, 579 Broadway, New York, on November 18, 1846, Dr. Alexander H. Stevens of the College of Physicians and Surgeons, responding to the toast "The Medical Colleges and Schools of Our Country" expressed the hope "That the increasing unanimity in the corps would lead soon to the establishment of a 'Medical Hall,' unconnected with hospitals or colleges, to contain meeting rooms, a library, etc., and be a place of general resort, both for ourselves and brethren from abroad."

In less than a year the New York Academy of Medicine held its first regular meeting. The meeting for organization was preceded by a published call signed by Dr. Valentine Mott, Dr. Alexander H. Stevens and Dr. Isaac Wood, representing respectively the Bellevue Medical College, the College of Physicians and Surgeons and the Medical Society of the County of New York. This meeting was held in the hall of the New York Lyceum of Natural History at 561 to 565 Broadway on December 12, 1846. Dr. John Stearns was elected chairman and Dr. F. Campbell Stewart secretary of the meeting. Dr. Mott, Dr. Stevens, Dr. John Watson, Dr. Manley, Dr. Riese, Dr. Cox, Dr. Wood, Dr. Francis and others spoke.

The following committee was appointed to prepare a constitution and by-laws: Drs. Francis, Bliss, Watson, Griscom, Benjamin, Drake, Barrowe, Riese, A. S. Purdy, J. R. Wood, and Tomes. Later Drs. Stevens, Mott and Isaac Wood were added to the committee which reported to a meeting held on January 6, 1847, at which the constitution and by-laws were adopted as submitted and were signed by one hundred and thirty physicians.

The objects of the Academy were set forth as:

First.—The separation of regular from irregular practitioners.

Second.—The association of the profession proper for purposes of mutual recognition and fellowship.

Third.—The promotion of the character, interests and honor of the fraternity, by maintaining the union and harmony of the regular profession of the city and its vicinity, and aiming to elevate the standards of medical education.

Fourth.—The cultivation and advancement of the science, by our united exertion for mutual improvement, and our contribution to medical literature.

Fellowship was restricted to regular practitioners of medicine or surgery in New York City or vicinity. Proprietors or venders of patent, or secret medicines or remedies were excluded from fellowship.

THE FIRST OFFICERS

A committee composed of Drs. Henry D. Bulkley, James R. Wood, Galen Carter, Willard Parker, and Edward L. Beadle was appointed to submit the names of three nominees for each of the offices to be filled. This committee reported at a meeting held on January 13, 1847, when the following officers were elected: President, Dr. John Stearns; vice-presidents, Drs. Francis U. Johnston, Thomas Cock, Sr., John B. Beck, and John W. Francis; recording secretary, Dr. Ferdinand C. Stewart; domestic corresponding secretary, Dr. William C. Roberts; foreign corresponding secretary, Dr. Benjamin Drake; treasurer, Dr. Robert Watts, and librarian, Dr. Thomas M. Markoe. At the next meeting held on January 20, Dr. Chandler R. Gilman, Dr. James Phelps, Dr. William P. Buel, Dr. Edward L. Beadle, and Dr. Luke Barker were appointed a committee to solicit donations of books for the library.

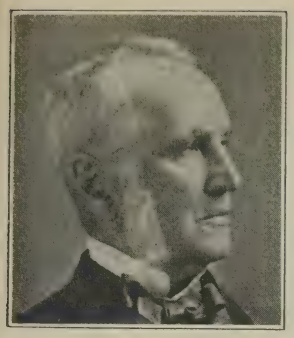
At the meeting, held on February 3rd, Dr. Stearns delivered his presidential address which was ordered published. The committee on books was instructed to provide a suitable seal and motto for the Academy. On February 24, Dr. John W. Francis was elected orator. On March 3, 1847, the last meeting was held in the Lyceum, quarters having been found in the Convention Hall at 179 Wooster Street, where the meetings were held until June 5, 1850.

The first anniversary discourse was delivered by Dr. John W. Francis at the Broadway Tabernacle. It was largely historical occupying some two hours in its delivery.

Below is given a list of the principal officers during the first thirty years, which may be looked upon as the formative stage of the institution. This list brings us down to the time when the Academy occupied its own building on Thirty-first Street.

Presidents: 1847, John Stearns; 1848, John W. Francis; 1849, Valentine Mott; 1850, Isaac Wood; 1851, Alexander H. Stevens; 1852, Thomas Cock; 1853, Isaac Wood; 1854, Joseph M. Smith; 1855, John W. Francis; 1856, Willard Parker; 1857, Valentine Mott; 1858, John P. Batchelder; 1859-60, John Watson; 1861-66 James Anderson; 1867-68, Alfred C. Post; 1869-70, Henry D. Bulkley; 1871-72, Edmund R. Peaslee; 1873-74, Austin Flint; 1875-78, Samuel S. Purple.

Treasurers: 1847, Robert Watts; 1848-1876,



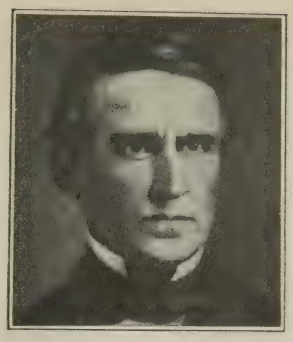
DR. WILLARD PARKER
President, 1856

James Otis Pond; 1877-1882, Horace Putnam Farnham.

Recording secretaries: 1847-1848, Ferdinand Campbell Stewart; 1849, John L. Vandervoort; 1850-51, John Glover Adams; 1852, Jackson Bolton; 1853-54, Samuel A. Purdy; 1855-56, Samuel Conant Foster; 1857-58, Charles F. Heywood; 1859-61, Theodore Gaillard Thomas; 1862-64, John H. Hinton; 1865-67, William M. Chamberlain; 1868-70, Edward H. Janes; 1871-76, William T. White; 1877-79, Edward F. Ward.

A complete list of the officers from the foundation to the present time would constitute an honor roll of medicine in New York, for its officers have ever been eminent in some field of medicine or surgery.

Below is given a list of the officers for 1926: President, Dr. Samuel A. Brown; vice-presidents, Dr. Herbert S. Carter, Dr. Frederick T. Van Beuren, Jr., Dr. Charles A. Elsberg; recording secretary, Dr. Fenwick Beekman; treasurer, Dr. Seth M. Milliken; trustees, Dr. Charles L. Dana, Dr. Fordyce B. St. John, Dr. Arthur B. Duel, Dr. George B. Wallace, Dr. Walter B. James, Dr. James A. Miller, Dr. George D. Stewart, Dr. Royal S. Haynes, Dr. Eugene H. Pool, Dr. Bernard Sachs; director, Dr. Linsly R. Williams; assistant secretary, Dr. Frederick P. Reynolds; librarian, Dr. Archibald Malloch; consulting librarian, Dr. Fielding H. Garrison; legal counsel, Frank L. Polk, Esq.



DR. JOHN WATSON
President, 1859-60

There is one official of the Academy, Mr. John S. Brownne, whose term of office has covered over forty years of its history and who has devoted his entire life to its service. A well deserved tribute to that service is paid by Dr. Delavan on another page and he himself tells elsewhere something of the story of the growth of the library from the first handful of books, donated in 1847 into the three hundred thousand titles which are now housed in the new building. Dr. Cushing and Dr. Thayer also pay eloquent tirbutes to the value of the library.

The Needs and Future of the Academy Library

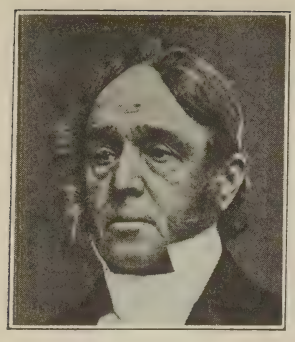
ARCHIBALD MALLOCH, M.D.
New York
Librarian of the Academy of Medicine

In the new building with more room and greater facilities for work, our duties and responsibilities will be greatly added to—and it is only right that they should be.

One of the most important of our responsibilities as an educational institution can only be met by our opening the library to the public—as distinguished from the Fellows of the Academy—for longer hours each day. It has been suggested that the public should have access to the reading and journal rooms up to five o'clock in the evening. This change will necessitate a larger staff to attend to the greater number of readers over a longer period of time and we must also meet the constant demands of cataloguing, and accessioning of books and pamphlets. With a periodical librarian placed in sole charge of the journal-room we hope to be able to inform Fellows, or other readers, on inquiry beforehand, of the appearance of articles (in whatsoever the language) upon subjects in which they have a special interest. With the increasing developments along certain lines of medical and philanthropic work the number of medical periodicals is bound to increase and we must needs subscribe to them or fall behind. Besides, there are certain Italian and Spanish magazines we must subscribe to. In Forty-third Street we were close to the library of the Chemical Society and could readily send readers over there to consult journals which we did not take. Having moved, however, we must subscribe to these chemical, and not purely medical, journals ourselves.

To increase the usefulness of the library for those whose work does not allow them much time to come to the Academy we should develop a motor call-and-delivery service. A Fellow should be able to telephone to the library for a book and have it delivered to his house or laboratory within a couple of hours. These demands will put further strain upon the staff of the library and upon our finances, but they are demands which must be met.

There is a great deal of work, work which may be called legitimate, which a library could perform for the writer of a paper and save him much time. It should consist of making lists of medical articles on a particular subject and getting the volumes containing these articles ready for the writer to see. After the writer has read over these articles in the languages which are understandable to him he should be able to have translations made and he should be able to call upon someone to copy out whole paragraphs where he wished to make long quotations. All this we trust we shall be able to do when we establish a bibliographical service, the plans for which are not yet completed. It need scarcely be said that if abstracts of articles are made by the bibliographical workers, the Academy cannot accept responsibility for their accuracy. We must not *write* medical articles but only *aid* in doing so. For this bibliographical



DR. ISAAC WOOD
President, 1850, 1853

service the Fellows must pay something, but probably at only about half the rate required of other readers. Possibly six to eight workers will be taken on the staff for this bibliographical work.

A machine is being installed in the new building so that photostats of rare pamphlets, books, or illustrations may be made on demand and sent out to any part of the United States and Canada. A new man will be employed part time for this work and probably part time for repairing books. Only if the volume of photostat work is very great will it, at moderate charges, pay for itself.

One of the most important educational possibilities of a library is the arranging of exhibitions of medical works, medals, engravings, instruments, etc., illustrating an important medical anniversary, the development of our knowledge of a certain disease, history of some branch of medicine in a special country, showing the artistic as well as medical value of early manuscripts and books on medicine, or illustrating, perhaps, the nonmedical activities—the avocations—of physicians. To appreciate thoroughly the work of those who have gone before us we must know the lives as well as the writings of those who wrought. The value of such exhibitions carefully planned cannot be easily gauged. The point here is, however, that to prepare for exhibitions of this kind requires many hours of careful research work, verifying of statements and dates, etc., and this must be undertaken by the staff.

A great need is to maintain the work which is done upon the "Union Check List of Periodicals." Only by noting on the shelves of libraries the number of years over which a certain obscure but valuable periodical sustained publication can it be definitely stated, to all who desire the information, the size of the gap which has to be filled. Because of the existence of this "Union Check List," work upon which is being carried out in the periodical stack of the Academy, we receive offers from bookdealers in the U. S. A. and Europe of chances to complete our sets of medical magazines. A bookseller in Germany, for example, notes from the list that we lack certain volumes of a certain periodical and he informs us that he can supply them.

Because our collection of periodicals, past and present, is very large, much time must be spent in the Academy upon the "Union Check List" and in this particular the larger are of great service to the smaller libraries. In the same way, we have great responsibilities in the possession of duplicates and triplicates of books, often bequeathed to us by physicians, for we must arrange to exchange or give these away to the smaller and less fortunate libraries. This work breaks in upon the time of the library staff.

It must be said that we could be of greater service to the medical men, say of Bronx and Queens, if we were to provide reading rooms, supplied with our books, in these boroughs.

DR. JOHN B. BECK
Vice-President, 1847

The time will come too, when it will be desirable to have our catalogue duplicated, printed that is, for the use of medical schools and for other libraries. Such a catalogue or bibliography justifies its existence when we realize that if any one of us, or any institution, does not possess a book on a certain subject it is impossible to know that such a book exists anywhere in the world unless we see it in a list. Specific requests could then be made of us by those living outside of the city.

In the future we should have lists of books ready on special subjects and, at the request of a struggling county medical society, we should be willing to send such collections of books. This arrangement would be of real educational value and who knows how many students we might encourage and how many practitioners we might induce to become "student-practitioners"—to use Osler's term—but we should bear part of the expense!

A library is judged chiefly by its general usefulness in supplying modern books and periodicals and those for as far back as a hundred years. But by other libraries and by the cultured and educated, a library is also judged by its possession of medical treasures in the guise of written or printed medical works. We are sadly lacking in the matter of manuscripts and there are many medical classics we need. Surely we should possess the greatest medical book—the 1628 edition of Harvey's *De Motu Cordis*—a Rabanus Maurus (1467), the first printed medical book, or the first edition of Celsus (1478). Prices are soaring up by leaps and bounds. If you ask: "Why is a facsimile not as good as an original?", we might reply with a Scottish answer, that is, with another question: "Is a copy of a painting as good as the original, is it as inspiring or as stimulating? No, the best is not too good for the Academy."

FINANCIAL NEEDS OF LIBRARY

We are fortunate in the possession of a number of interesting medical incunabula. The books printed before 1501 are constantly becoming more rare.

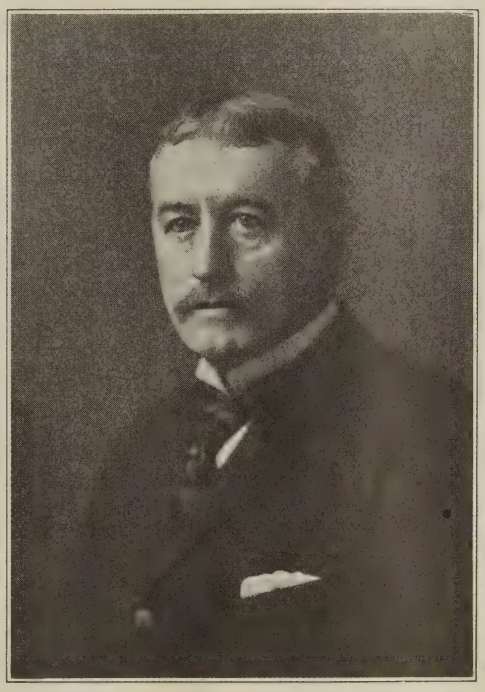
The present library endowment is $165,000 and the income from this endowment plus the income from the Witthaus estate is approximately $15,000 a year. It is estimated that it will cost in addition to this endowment and to the funds already being appropriated by the Academy, $37,500 a year, or the income of $750,000 additional endowment. We will need an additional $8,000 a year for books, journals and binding; $200,000 endowment for salaries of the library staff; and the income from $390,000 for additional salaries of personnel and administration expenses. This is a large sum of money and the income will be difficult to obtain from the Fellows of the Academy, but if anything can be obtained by the Academy for the additional endowment of the Library, it will materially relieve the burden which will be placed on the Fellows for the maintenance and operation of the new building.

The Retiring Librarian of the Academy of Medicine

D. BRYSON DELAVAN, M.D.
New York

In the course of an address on the Founders and Early History of the New York Academy of Medicine, delivered at its last Anniversary meeting, I called attention to the lifelong service rendered the Academy by its Consulting Librarian and Superintendent, since retired from active service. It now affords me pleasure to repeat here that tribute to a learned and highly efficient executive and a much esteemed friend.

The first permanent home of the New York Academy of Medicine at No. 12 West Thirty-first Street, was taken possession of by it in 1875. Within five years the number of books amounted to 25,000 and the other activities and responsibilities had become important. All the work connected with them had been carried on by a small group of its most zealous members, chief among whom were Dr. S. S. Purple and Dr. Laurence Johnson, who soon found themselves overburdened. The services of a professional Librarian and General Superintendent had become imperative. In the year 1880, one was secured, and from that time the history of the Academy has been intimately identified with the life experience of that man. For nearly half a century since there has been behind its steady growth and prosperity his influence, which has contributed vastly to its success.



JOHN S. BROWNNE
Consulting Librarian

Quietly, without a suggestion of selfinterest or obtrusiveness, that influence has been exerted for the upbuilding of our institution, with a singleness of purpose and a steadfastness of devotion for which it would be hard to find a parallel. To it, more than to any other individual factor, is due not only our material prosperity, but, even more important, that spirit of harmony which has characterized the Academy's contemporary existence. Men and groups of men in ever succeeding administrations have come and gone, each faithfully and efficiently accomplishing their individual work. This influence, exerted with intelligence and wisdom, and with complete knowledge of all that had gone before, has caused each administration to glide quietly into the next, without friction and with no interruption to the routine. The supervision of the servants and of the building, the routine of the accounts, all have come under the hand and eye of that one executive, who, with the highly intelligent aid of his genial, versatile and indefatigable assistant superintendent, Felix Wesstrom, in the execution of the details of the management has conducted the material affairs of the Academy with admirable quietness but with complete and uninterrupted success. Ever zealous in giving all possible aid, it was he who, representing the Academy, courteously received its casual visitors, aided in the plans for the entertainment of those especially honored, and in the arrangements for unusual functions of every kind. He it was to whom all of us resorted for information covering the entire range of medicine in general and the various activities associated with it, rarely failing to gain from him the desired knowledge or else to be directed with sympathetic courtesy to where it might be found.

The character and personality of the man have invariably attracted the best of those who have known him, both of the medical profession and of the laity, here and everywhere. He has gained not only their confidence and friendship but their unqualified support, encouraging where encouragement was helpful, aiding by wise suggestion when consulted, and by hearty cooperation in the execution of the work; thus in every way strengthening the institution. Through all the varying phases of nearly half a century, he has been the unfailing pilot of the Academy, its unwearying helper and friend. You, who know the Academy, will not need to be reminded that I am speaking of our Consulting Librarian and Superintendent, Mr. John S. Brownne, beloved and honored of us all.

Mr. Brownne comes of fine ancestry. His grandfather, Charles Brownne, a ship builder by profession, came from England early in the last century and established a shipyard in New York City. He was commissioned by Robert Fulton to build the *Claremont,* and thus became the maker of the first steamboat on record. Mr. Brownne's father, Robert H. Brownne, was Secretary and Librarian of the New York Lyceum of Natural History, the most influential scientific society of its time, itself an Academy in the highest acceptance of the word. From it was developed the now famous New York Academy of Science. Its membership included men of distinction in various departments of learning, among them Dr. Torrey, the well known founder of the New York Botanical Society, as well as a group of leading physicians who, taking their inspiration from the successful methods of the Lyceum and, as aforesaid, following the example of the Academy of Medicine

of Paris, conceived and developed our own Academy of Medicine.

Mr. John S. Brownne was born in King Street, Greenwich Village, New York, and after receiving an excellent education gained a position as Assistant Librarian in the Astor Library. When the Academy of Medicine moved into its new building in Thirty-first Street, its farsighted officers soon recognized the possibilities of its growth and, upon the completion of Du Bois Hall in 1880, the necessity for a competent manager. Mr. Brownne's qualifications were carefully studied by them, and after long deliberation he was selected from among thirty other applicants. Already familiar with the routine of library work, and fully informed as to the intentions and ambitions of the Library Committee of the Academy, he entered upon the duties of his office with full appreciation of the magnitude of the enterprise and of its responsibilities, and a clearly expressed determination to make the infant project the best medical library in the world. In this ambition he had the enthusiastic support of the officers of the Academy, a group of physicians who possessed the culture, the knowledge, and the influence to bring about the desired results.

Books in considerable number were given by members, among whom was Dr. Purple, an ardent collector. For many years he had gathered complete files of American medical periodicals, until he had acquired the most nearly perfect series in existence. These he presented to the Academy. Dr. Fordyce Barker was also a generous donor.

Some years before the Academy moved into the Thirty-first Street building, Dr. Frank P. Foster, editor of the *New York Medical Journal,* had established a society known as the Medical Journal Association, which had its quarters in the building 107 East Twenty-eighth Street, at that time as now occupied by Tiemann and Company. By a friendly arrangement, the Journal Association was merged into the Academy, where it occupied the third floor of the new building and at once created for the institution its department of current periodicals.

Under the zealous efforts of Mr. Brownne, the Library increased rapidly in volume and in importance. Soon after the date of his appointment, Dr. John S. Billings was made Librarian of the Library of the Surgeon General of the United States Army in Washington, and thus at once Mr. Brownne found himself confronted by a powerful rival, as shown in the competition between them for desirable accessions. In these competitions Mr. Brownne often outbid his rival, funds being provided by enthusiastic members or by their generous friends. The most important acquisition came through the Governors of the New York Hospital who, in 1898, donated to the Academy the Library of the New York Hospital, numbering 23,000 volumes, a fine collection founded in 1798, in its last half century under the able direction of its Librarian, Mr. John L. Vandervoort.

This included the celebrated collection of rare old books on the history of medicine made by Dr. John Watson, which was the beginning of the Academy's present fine collection of incunabula.

Dr. Watson's anniversary address on "The History of Medicine" was the valuable contribution of a ripe scholar who had ample sources of reference in his own library.

Year by year, with steady increase, the Academy gained in reputation and influence. Its reliability was recognized, the dignity of its ambition appreciated. The growth of its Library, according to the record, eloquently proves the esteem in which it was held. The total books in 1875 amounted to 21,720; in 1880 to 25,000; in 1900 to 49,830, and in 1910 to 80,790. In 1926 there were 139,320 books, 98,685 pamphlets, while 1,500 were journals subscribed for, making a total of 239,505 titles.

All of this has come about under the administration of Mr. Brownne, aided by various efficient library committees and by the talent and devotion of his invaluable associate of thirty-five years, Mrs. Laura E. Smith. They, throughout this long period of activity, have been the soul, the spirit of the Academy, quietly furthering its progress with rare wisdom and tact. If the fame accorded to Dr. Billings for the upbuilding of the second greatest medical library in the world is justly deserved, then equal credit is due to our own Librarian for the success of his life work in creating the Library of the Academy as it stands today, the third greatest of its kind, perfectly ordered and arranged according to the most advanced ideas of modern library organization.

Library of the New York Academy of Medicine

JOHN S. BROWNNE
Consultant Librarian

While my duties have embodied the management of the buildings of the Academy in which I have lived for more than forty years and in which my two children were born, my chief interest has been centred in the library. From the very foundation of the Academy its leaders have appreciated the important service that a library could render to the medical profession. After the organization had been effected in 1847 the first committee appointed was one charged with soliciting contributions of books to the library. That committee consisted of C. R. Gilman, James Phelps, William P. Buel, Edward L. Beadle and Luke Barker.

A circular requesting the donation of books and periodicals to the Academy was issued by this committee in January, 1847. This was addressed to the medical profession at large as well as to the fellows of the Academy. Many donations were received and a substantial nucleus for a library was obtained. But, there being no permanent place for the deposit of the books, the efforts were discontinued.

When in 1875 permanent quarters were provided in Thirty-first Street, a library committee was again appointed and became active under the stimulus of the enthusiasm of Samuel S. Purple. His presidential address two years later was devoted mainly to a

survey of medical libraries in New York. From this address we learn that a medical society existed in New York City before the Revolution but suspended operations in 1776 when the British captured New York. This was resuscitated in 1784. The first mention of its library occurs in 1787. The Medical Society of the State of New York was organized in 1794 and this society purchased the library of the Medical Society in December of that year. This was placed in charge of Dr. David Hosack as librarian on January 13, 1795, subject to the rules of the City Library then located in the City Hall. The medical library was moved to the City Hall the following summer. In 1806 this library was made over to the Governors of New York Hospital, which had already established a library of its own in 1796 in accordance with a suggestion from the faculty of Columbia College and had appropriated five hundred dollars towards that end.

In his inaugural address as the first president of the Medical Society of the County of New York in 1824, Dr. Hosack urged the creation of a library by that society. This project was adverted to from time to time. Dr. Peixotto in his inaugural address as president in 1831 said that "little success has as yet attended the attempt to form a library worthy of the character of our city or adequate to supply the wants of an extended medical community. The time has, however, arrived when we may, without exaggerated hopes, set about instituting a New York Medical Society Library." Several hundred volumes were collected and kept at the home of the secretary, Henry S. Downs. These books were sold in 1862.

Office of the Assistant Librarian, showing the antique desk, once a part of the office furniture of Dr. Timothy M. Cheesman, and willed by him to the Academy.

The New York Hospital had purchased the library of Dr. Romayne in 1800 and the great botanical library of Dr. Hosack and in 1877 this library had grown to nearly ten thousand volumes. Valentine Mott's will provided that his books and instruments be kept together during the life of his widow who might bequeath them to any grandson bearing his name who should become a physician. These with the books of the late Isaac Wood constituted the Mott Memorial Medical and Surgical Library, which was later acquired by the Academy. Other medical libraries of that time were those of Bellevue Hospital, about 350 volumes, of the College of Physicians and Surgeons, about twelve hundred volumes, and of the College of Pharmacy of the City of New York, about twelve hundred volumes, besides current periodicals. The Mercantile Library had about one thousand medical books and the New York Society about the same number. The largest collection of books on medicine and the collateral sciences was that of the Astor Library about seven thousand. There was also a Medical Journal Association whose purpose was to provide for the circulation of current periodicals among the members. This association under the leadership of Dr. Frank P. Foster, editor of the NEW YORK MEDICAL JOURNAL, was later merged with the library of the Academy.

Dr. Purple urged that an attempt be made to collate these medical books into one great medical library under the direction of the Academy.

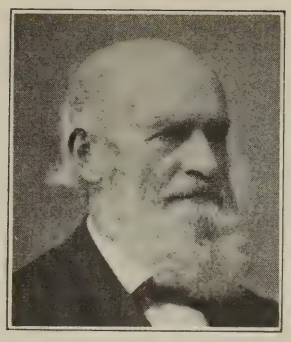
Under the stimulus of Dr. Purple's leadership and of a permanent home the library of the Academy grew rapidly. The use of the library was made free to all, and in his valedictory address in 1879 he recorded the rapid growth of the library and in the number of readers. He further proposed the establishment of a circulation department.

By 1880, when I came to the Academy, the library had grown to twenty-five thousand volumes. The large and valuable collection of Freeman J. Bumstead was bequeathed to the library in 1881. Since that time many libraries have been bequeathed to the Academy by former Fellows, among the most valuable of which may be named those of Thomas H. Allan, John O. Stone, Edward L. Beadle, and Abraham Jacobi; Dr. Purple, Fordyce Barker and Abram Dubois donated their libraries before instead of after death. The German Hospital and Dispensary sold its library to the Kings County Medical Society and donated the proceeds to the Academy. The most important of these donations was that of the library of the New York Hospital. This library of 23,000 volumes had been founded in 1796 and included the celebrated collection of rare old books on the history of medicine made by John Watson, whose anniversary address in 1860 on this subject was a most scholarly discourse. Dr. Watson's library provided the nucleus of the fine collection of medical incunabula in which the Academy library ranks third in the United States. The Academy has nearly one hundred of these books printed prior to 1500, one of which is the only copy in America, while several of them are extremely rare.

Beside books many members have either given or bequeathed money to the library fund. The following list of library funds as it appears in the report of the treasurer for 1925 shows such of these as have been maintained as separate, individual funds.

LIBRARY FUNDS

Below is given a list of the several library funds in round numbers: General Library Fund, $41,606; J. Marion Sims, $100; James S. Cushman, $1,000; Orville R. Flower, $1,000; Anna Woenshofer, $15,000; William T. Lusk, $1,000; Semicentennial Committee, $500; German Hospital and Dispensary, $3,076; Albert W. Warden, $950; Landon Carter



DR. ALFRED CHARLES POST
President, 1867-68

Gray, $45,596; Rudolf A. Witthaus (ultimate residuary legacy estimated), $120,000; Everett Herrick, $25,000; Phillippine Meyer and Ernst Jacobi, $14,486; Merrill Whitney Williams, $220; Ernest Krackowizer, $1,798; Austin Flint, $1,200; Bullowa, $754; A. L. Northrop, $250; James P. Tuttle, $1,000.

Professor Rudolf Witthaus left a large estate from which the library receives five thousand dollars a year. He left other heirs incomes for life. After the death of these beneficiaries his entire estate is to revert to the Academy.

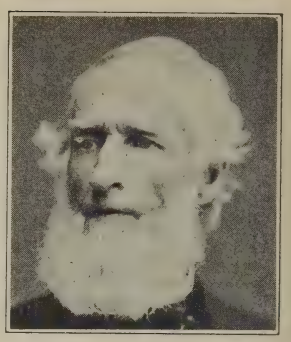
The increasing rapidity with which the library has grown is shown by the following figures:

1875	Books	21,720
1880	Books	25,000
1900	Books	49,830
1926	Books	139,320
1926	Pamphlets	98,685
1926	Journals subscribed for	1,500

The total titles including pamphlets and journals at the close of 1925 amounted to 239,505.

The mere possession of books make a large library. It is the use to which they are put that makes the library of value. Realizing this fact, the New York Academy of Medicine has always pursued a most liberal policy throwing open its doors to all for free consultation during the morning hours, though reserving the later hours of the day for Fellows. The loan of books to Fellows is encouraged in every way. List of new accessions are distributed to the fellows semimonthly and expert assistance is rendered to such as are engaged in bibliographical research. In such rapidly developing fields as medicine and surgery such research is of very great importance as a basis for original experiment and study. First of all the physician or surgeon must know what others have done so that he may avoid unnecessary duplication in his own work.

Assistance is rendered first of all by the general card index of the contents of the library which is divided into two sections, a subject index and an author index. To the professional librarian this may sound like an heretical practice; but experience has shown that this arrangement minimizes and facilitates the labor of those who use the index most.



DR. EDMOND RANDOLPH PEASLEE
President, 1871-72

Next we have complete files of the *Index Medicus* issued quarterly by the Surgeon General's Library, and the *Quarterly Cumulative Index* issued by the American Medical Association. These index both books and current periodical literature.

In the handsome room reserved for Fellows all accessions to the library are placed on open shelves for a certain time so that those who choose may see the new books as they arrive before they go to the book stacks.

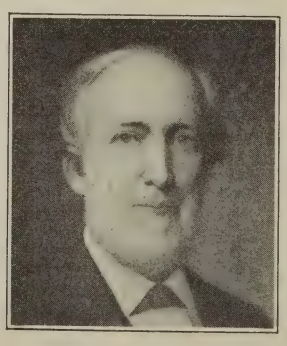
Some 1500 current medical periodicals in all the modern languages are of convenient access to all, whether Fellows or not, in the current periodical room, while in the adjoining room bound volumes of the recent years of those periodicals most called for are kept on easily accessible open shelves.

In relinquishing the task which for forty-five years has filled every minute of my waking hours, I do so with the joy that comes only to workers, the joy of achievement; with delightful memories of the long line of learned, scholarly, gentlemen with whom that work has brought me into friendly intercourse and of grateful appreciation for the expressions of friendly esteem and appreciation which have been brought out by my retirement. From that retirement I shall continue to watch with pride and affection the still greater growth and widening usefulness that surely awaits the New York Academy of Medicine and its library.

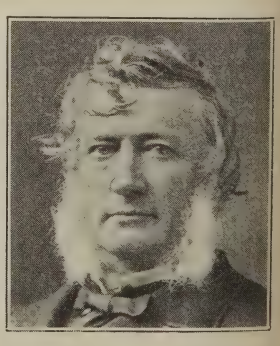
To those whose faithful cooperation with me has contributed so largely to the success of the library I wish to express here my sincere appreciation for this loyal and intelligent assistance. It will not be an invidious distinction for me to name one in particular, Mrs. Laura E. Smith, who has been my willing, intelligent and untiring coworker for the welfare of the library for the past thirty-five years.

DR. HORACE P. FARNHAM
Treasurer, 1877-82

DR. AUSTIN FLINT
President, 1873-74



DR. SAMUEL S. PURPLE
President, 1875-78



DR. BENJAMIN FORDYCE BARKER
President, 1879-84

Main Hallway, Showing Entrance from 103rd Street

Art and Architecture of the Academy of Medicine's New Home

MABEL WEBSTER BROWN
New York

Beauty, comfort and convenience, healthfulness, and adaptability to the greatest possible utility, growth and progress, are, in every civilized land, the recognized standards of a house or home, whether it be the habitation of an individual, a family, an institution or organization, or a community. Eighty years ago a realization of the value of these standards was in the mind of Dr. John Watson, who, on the evening of December 12, 1846, addressed a meeting of the medical profession of New York City, called to discuss "the establishment of a Medical Hall, unconnected with hospitals or colleges, to contain meeting rooms, a library, etc., and to be a place of general resort for ourselves and for our brethren from abroad." Dr. Watson said that the imperfect action of a medical body depends upon the want of a proper place of meeting; if the profession would all set to work, they would soon have an ornamental and useful one; that he hoped the time was not far distant when the medical clubs, or private societies, would come together; if so, the profession would be organized and subject to no reproach. Twenty years later Dr. James Anderson said, in addressing the then established New York Academy of Medicine: "The great duty now resting upon us is that we secure a site and erect a building thereon that shall not only be an ornament to the city, but an honor to the Academy and the profession—a Great Medical Centre, that shall be both attractive and scientific." This ideal, of a combination in its home of beauty, use, and adaptability to scientific progress, have remained constant in the minds of the Fellows and friends of the New York Academy of Medicine since its official founding on January 6, 1847, up to today, and have attained their highest and most complete fulfillment in the beautiful new building, opened to Fellows and the public on November 18, 1926.

The earliest homes of the New York Academy of Medicine were of necessity small and simple. The first meeting was held in a room of the Lyceum of Natural History at 561 Broadway, at that time the representative scientific institution of the city. From March, 1847, until June, 1850, a rather inconveniently located and uncomfortable room in Convention

Hall, Wooster Street, was used. Considerable improvement was shown in the next meeting place, from 1850 to 1860, which was the building of the University of the City of New York, on the east side of Washington Square. This temporary home was a fairly attractive one and the meetings were well attended. The next meeting place was the College of Physicians and Surgons, at the corner of Fourth Avenue and Twenty-third Street.

Members who possessed libraries now began to donate them to the Academy, so the need for more room soon became an urgent one, and finally led to the Academy's acquiring its first separate home, a private dwelling with a brown stone front which was adapted to meet the requirements. The location was at 12 West Thirty-first Street, and the first meeting was held there on May 20, 1875. The house consisted of four stories and basement, and, for five years, provided commodious accommodations for meetings, the fast growing library, and other purposes. In 1880, however, the necessity for a larger meeting hall became imperious, with the result that Dr. DuBois authorized the construction of an annex at the rear of the building. This hall was given his name.

In a few years the increasing number of members and activities of the Academy, and the still rapidly growing library, made the Thirty-first Street building totally inadequate, and a lot on West Forty-third Street was purchased. A six story fireproof stone building in modified Romanesque style was completed in 1890. By 1910 the library had grown to such an extent that, for its proper accommodation, two houses adjacent to the building were purchased and part of one of them used as an additional stack room. This building contained among its rooms Hosack Hall, given in memory of Dr. Alexander E. Hosack by his widow, Mrs. Céline B. Hosack, and Woerishoffer Hall, given by Mrs. Anna Woerishoffer in memory of her husband, Dr. Charles F. Woerishoffer. These halls have been perpetuated in the present building of the Academy. It housed also the offices of a number of related organizations.

Very soon, however, the building on Forty-third Street, which had seemed so ample to meet all needs for an indefinite period, had become insufficient for housing the Academy activities and its still rapidly growing library, so steps were taken which led in the end to the present beautiful structure on Fifth Avenue. The story of how this came about is told elsewhere. We are now ready to visit this new home.

The site is the southeast corner of Fifth Avenue and 103rd Street, insuring comparative freedom from the city's increasing dirt, dust and smoke, and providing an abundance of light, fresh air, and sunshine. Of these last, the building can never be deprived, since Central Park on the west will afford a permanent supply, as well as a very pleasing outlook over the botanical gardens in the foreground to the lawns and foliage of the park beyond.

EXTERIOR OF THE BUILDING

The main portion of the building on Fifth Avenue is made up of six stories besides a basement and subbasement. The auditorium wing on 103rd Street is three stories in height. The architectural style is early Romanesque, an art form which lends itself readily to the principles of modern building construction, as well as to appropriate decorative modifications. The tenets of the style, which originated in Italy, have been carried out both as to the exterior, and, in so far as was possible, in the interior of the building. The plain, rectangular shape, giving simplicity of form, has been relieved by the appropriate use of rich and ornate sculptural decorations, grill work, colonnades, and a rather elaborate entrance, all in keeping with the period.

Main Entrance on 103rd Street

The stone used for the walls is a combination of varieties of limestone and sandstone, giving an effect of pale yet warm creams, tans, and white to the exterior. An attractive color note is added by the blue green window casings. The windows on the ground floor are ornamented and protected by handsome bronze grills in Romanesque decorative design. At the upper corners of each window are ornamental imposts sculptured in bas-relief with figures from medical emblemology and mythology, such as various aspects of Æsculapius and Hygeia, of Typhon or Typhoeus, the mythological god of pestilence, and various animals having a significance in medical symbolism. Above each window on the first floor is inscribed in Latin a legend appropriate to the art of medicine. A frieze of large Roman letters encircles the third story which tells us: Vita Brevis: Ars Longa: Experentia Fallax: Judicium Difficile (Life is short; art is long; experience untrustworthy; judgment difficult); and Homines Ad Deos Nulla Re Proprius Accedunt Quam Salutem Hom Dando (Men in no way approach so nearly to the gods as in giving

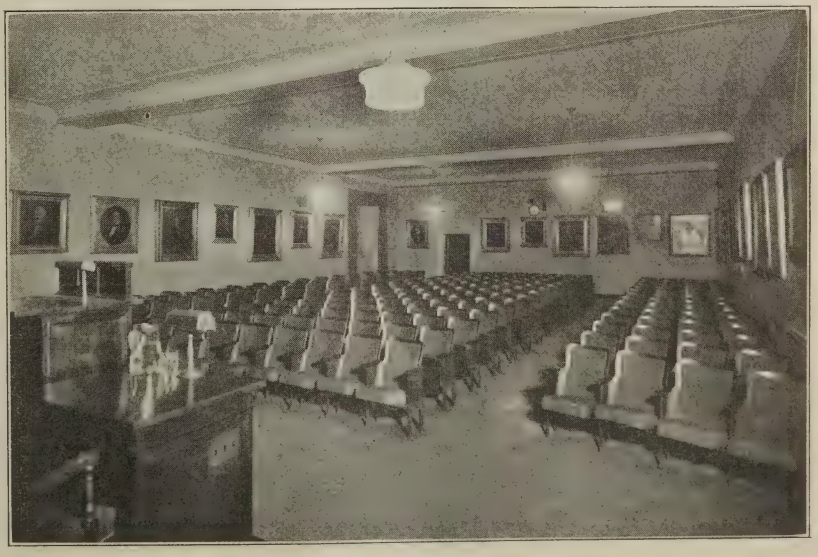
A corner of Farnam Hall, the Current Periodical Room, in the Library

health to men); on the front elevation of the building are the name of the Academy, Academia Medicinæ Nova Eboracensis, and the date of founding. The windows in the third story and in the auditorium wing are large and have the high, round arches which are one of the distinguishing characteristics of the Romanesque period. The sixth story, and the third story of the auditorium wing, are encircled with colonnades of Romanesque pillars.

The entrance to the building, which is on 103rd Street, is one of its handsomest features. The doorway is flanked by cloistered columns with ornate Romanesque caps, surmounted on either side with figures of lions. The tympanum, sculptured in mezzo-relief, shows a meeting of Æsculapius with his daughter, Hygeia, with the staff and serpent between them, and both accompanied by their faithful dogs, which, in medical symbolism, typify the spirit of watchfulness which drives away the death fiend. Hygeia carries her constant attribute, the bowl or *patera;* Æsculapius is represented, as was usual in antiquity, with his torso undraped so as to leave free his arms and hands for his medical work. This piece of sculpture is of unusual artistic merit, and suggests the classic style of art in its simplicity, dignity and beauty. Directly above the doorway is the legend: Post Mille Secula Præscinditur Occasio Aliquid Adjiciendi (After thousands of ages the opportunity persists of adding to our knowledge). On either side of this inscription are medallions in bas-relief with heads of Hippocrates and Galen. The outer entrance doors are of ornate bronze grill work of floral design, with small figures of Æsculapius and Hygeia. The inner doors are of solid bronze, panelled. There are two other entrances on 103rd Street, one for service.

ENTRANCE HALL

Entering the building, we pass through a small vestibule into the main hallway, and are struck at once with the richness and beauty of its decorations and furnishings. The floor is of reddish veined Levanto marble, with a border of white Traniville, inlaid with a mosaic pattern made of many kinds of variegated marbles. In the floor are bronze inserts representing the squirrel, rabbit, guineapig, dog, and the trifoliate mandrake leaf, all related to the science of medicine, and combined in design with herbal patterns. The walls are of cream colored Mankato marble. A broad stairway of Traniville marble leads up on the left to the second floor. There are also three elevators, these on the right. Bronze doors open into the information bureau, Hosack Hall, the Exhibit and Collation Room, the Reception Room, and a stairway at the rear. Just outside the entrance to Hosack Hall is an inscription on the wall listing the benefactors of the Academy. Other inscriptions will be added, including an expression of gratitude to the Rockefeller Foundation and to the Carnegie Corporation for their most generous contributions to the Academy; and a memorial tablet to the Fellows of the Academy who died or gave their services during the World War. The ceiling of the hallway is square-beamed, with rich, handpainted designs in warm colors, red and gold predominating. These combine arabesque patterns, derived from the medical symbolism of the Herbal School of Salernum, with representations of the many small animals and birds, which, through the ages, have come to be associated in some way with the art and science of medicine. These include the dog, whose significance has already been mentioned; the serpent, the symbol of the god, Æsculapius, himself, and signifying prudence, longevity and rejuvenation, and oftentimes, especially

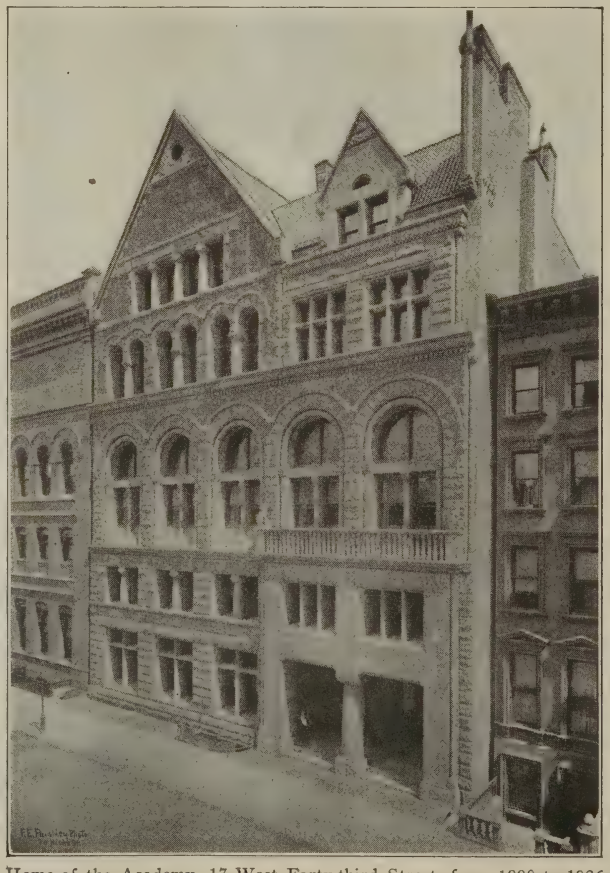


One of the Section Meeting Rooms

in the countries, such as Egypt, where serpent worship prevailed, the actual curing of disease; the cock, he who watches for returning day, the restorer of health, and also the symbol of fatherhood; the goose, symbol of motherhood; the goat, signifying lust, brutish reproductive powers; and other birds and beasts. Among the herbal symbols appearing most frequently is the mandrake, that baleful weed, which utters screams when it is pulled up so horrid that whosoever hears them goes mad, yet in some countries has been credited with having curative properties; the pinecone, symbolizing "the life of charm," whose aroma is "the breath of life," and which is sometimes represented as adorning the ends of the branches of the Tree of Life; and the Tree of Life itself. All these and other symbols and emblems have been combined into delicate and richly colored arabesque patterns and designs that make the ceiling of the hallway and those of some of the larger rooms a delight to the eye and also to the inquiring mind interested in the history of medicine throughout the ages. The only furniture in the hall is a long walnut table in Romanesque design, with two large bronze standard lamps, and some handsome tapestry chairs. The lights are bronze electric candelabra on the walls.

Home of the Academy from 1875 to 1889, 12 West Thirty-first Street

As we enter, a door on our right leads into the reception room for Fellows. This has gray green walls in brush-stippled effects, with carpet, furniture, and draperies in different shades of brown and tan. It is furnished with easy chairs, davenports, and all accessories for comfort and sociability. Here appointments can be held, friends may meet for business or pleasure, and smoke and talk at will. On the left of the entrance is the Information Bureau with its bulletin boards, etc. At the right, beyond the reception room, is the Exhibit and Collation Room, done in shades of brown, and adorned with bronze busts and oil portraits. Between the two is a modern tiled pantry with every appointment for prompt and efficient service, with a well equipped kitchen below.



Home of the Academy, 17 West Forty-third Street, from 1890 to 1926

HOSACK HALL

To the east of the entrance hall is Hosack Hall, the auditorium for the building, with its seating capacity of 700. This was the largest hall in the Academy's building at Forty-third Street, and is next to the largest in the present building. This hall carries out the original wishes of its donor, Mrs. Céline B. Hosack, who presented it to the Forty-third Street building in memory of her husband, Dr. Alexander B. Hosack. Dr. Abraham Du Bois was instrumental in bringing about the original gift. There is a lobby to Hosack Hall with walls of beautiful blue and gray veined Onondago marble, colors which harmonize with the decorations of the hall itself. The walls of the hall, the height of which is equivalent to two stories, are finished in tan stone effects, with high, round-arched windows on the north and south, the frames of which are surrounded with decorative sculptured borders. The keystone of the proscenium is a tablet with an inscription commemorating the donor of the hall; around the proscenium is the same type of decorative border that surrounds the windows. Figures from medical symbolism and allegory are combined in these with floral design. A good sized balcony at the back of the hall provides more seats and a moving picture operator's room is concealed behind the balcony. The draperies of Hosack Hall are old blue and gold brocade, and the carpet is in two shades of brown. The seats are upholstered in blue. Lighting is from chandeliers and from wall candelabra. Those who have seen this hall have commented upon it as the most beautiful of its kind in New York City.

On the second floor is the entrance to the balcony of the auditorium, the moving picture operator's booth, a large lecture room with moving picture screen and booth, dental amphitheatre, rooms for clinical demonstrations, patient's dressing rooms, and several section meeting rooms and offices.

The section meeting rooms are unique in their appointments for utility and up to dateness. Each is equipped with a slid-

Woerishoffer Hall, the General Reading Room of the Library

ing blackboard back of the speaker's platform, a cork wall board for attaching objects for demonstration, and a lantern for slides. Every provision for comfort is made, including upholstered seats, and all facilities supplied for clinical demonstrations and examination of patients.

THE LIBRARY

Practically the whole of the third floor is occupied by the library. The entrance is through the circulation department, a handsome hall with a dark panelled wainscoting and walls in tan paper-stippled effects. The charging desk, catalogue case, and other appointments are in walnut, and the floors of soundless compressed ground cork in shades of dark brown. In front of us as we enter is the doorway into Woerishoffer Hall, and beside it an inscription commemorating the donor. Woerishoffer Hall is the largest room in the new building and is the general reading room of the library containing the later volumes of the collection of bound periodicals. It is high-storied, with large arched windows, and handsome beamed ceiling painted with the same type of arabesque already described. At the windows are heavy brocade lambrequins in dull red and gold with tan inner curtains. The furniture here, as is the case throughout the whole building, was specially designed to be in keeping with the period, as well as to fulfill its various uses. There are large bronze standard reading lamps with tan silk shades on the long tables for readers. Across the centre of the hall is a double row of exhibit cases, now containing some interesting material from early medical Americana. The floor of the hall, and of the adjoining rooms, is of cork, with a border of white and verde antique marble.

With its outlook toward the west over Central Park is Farnam Hall, named in memory of Dr. Horace Putnam Farnam. This room is decorated similarly to Woerishoffer Hall, and contains the current periodical collection of the library, for the use of which it is equipped with readers' tables and wall and floor shelves. In addition to these two main reading rooms, the library contains a room for old, rare and valuable works; a room for medical history and bibliography; the Fellows' room, adjoining the circulation department, where members may retire to read, write, or smoke, and where they will find for their use the latest accessions of the library displayed on the shelves; the librarian's office; the assistant librarian's office; and the library cataloguing and work room.

The whole southeast section of the building, from the sub-basement to the top, consists of the book stack. This is in nine stories, with shelving of cast iron similar to that which is being installed in the new wing of the Library of Congress at Washington.

There is an electric elevator and book lift. The floors and stairways are of Kasota stone. The seventh, eighth and ninth stack floors are equipped with curtained study cubicles, each with its own window and radiator, table desk, chair and drop light. There are stairways at either end of the stack. One of the chief features of the stack is that it is not a fixed unit, but may be expanded to an almost indefinite capacity. It is so built, if desirable, eight additional stories may be added above, and an extension at the rear.

THE UPPER FLOORS

The third floor mezzanine consists of eight good-sized seminar rooms for members, equipped with tables, chairs, droplights, etc. Here members may work, confer, or have special typing or stenographic work done, a service which the Academy is planning to supply in the near future.

The fourth floor contains the offices of the New York State Medical Society, the American Otological Association, and the Association for the Relief of Widows and Orphans of Medical Men, section meeting rooms, and various offices.

The fifth floor houses the headquarters of the New York County Medical Society, The Physicians' Mutual Aid Society, the *New York State Medical Journal,* the First District Dental Society, and the Hospital Information Bureau, as well containing several section meeting rooms, offices, waiting rooms, etc.

The sixth and topmost story contains the administrative and executive offices of the Academy, including the office of the Director, the Committee on Medical Education, the Public Health Committee, and the Committee on Admission. It is also the headquarters of the Bureau of Clinical Information. On this floor is located also the Council Room, handsomely furnished and decorated, with walls of tan antiques and draperies, a rich ultramarine rug, and chairs upholstered in dull green materials. A smaller room, furnished similarly, is to be used for committee meetings, both by the Academy and other organizations.

On this floor are also the staff rest room, lavatory, kitchen and dining room, all comfortably and attractively furnished. The kitchen is equipped with a gas range, refrigerator, elaborate enamel kitchen cabinet, full set of dishes, and other conveniences. The telephone operator's office is also on the sixth floor, with a switchboard with fifty extensions in the building alone.

OTHER FEATURES

The building is completely fireproof, heated with steam and ventilated by the Univent System of ventilation. The hallways are spacious, well lighted, and have floors of Travatine terrazzo with gilt interlinings. The walls of the upper hallways and of the various offices are all in brush-stippled effects. There are lavatories, coatrooms, telephone booths, etc., on the various floors for the use of members and physicians in the building. The sanitary appointments are very complete, and are of the latest and most approved type, as well as handsome in appearance. There is a complete photostat equipment in the basement for the use of Fellows and physicians.

In order that their home may be a permanent one and at the same time keep pace with its own growth and with the progress of medical science the Academy has provided for expansion of its buildings in various ways. Additions may be made on top of the structure to as great a height as is permitted by the city (probably four stories). Four stories may be added on top of the auditorium wing. Eight additional floors may be added to the book stack, so that it may house in the future approximately a million books and pamphlets. Last, an extra plot of ground at the rear of the Academy has been purchased, and is to be used at present for the parking of cars, but may in the future be devoted, if necessary, to building purposes.

Now that we have passed in rather rapid review over all these utilities, beauties, and forms of service to humanity that are embodied in this new home of the New York Academy of Medicine, we are convinced that these men have even "builded better than they knew," and that their ideal, stated eighty years ago at that preliminary meeting of a few interested and faithful souls at Peletier's on lower Broadway, and kept steadfastly before the minds and hearts of their successors throughout the years, has borne rich and abundant fruit such as was not even dreamed of by those who planted the seed. Yet it is to them primarily, to those also who have cultivated the ground, and finally to the generous benefactors, who with their gifts have made dreams come true, that this great and beautiful monument to and source of unending service to humanity has been made possible to our Great City and the scientific world.

News Items.

Specialist in Pathology Needed at Iowa Hospital.—The U. S. Civil Service Commission states that there is a vacancy in a position of specialist in pathology at the Veterans' Bureau Hospital at Knoxville, Iowa, and that applications are being received for the position. The entrance salary is $3,800 a year. Promotion to higher grades may be made in accordance with civil service rules. Full information and application blanks may be obtained from the U. S. Civil Service Commission, Washington, D. C.

Columbia Medical Service to Be Extended.—Announcement has been made that Columbia University will build a medical service building, and, when facilities are available, that all students at the university will be required to undergo a medical examination. It has also been announced that the infirmary for men, equipped to care for 1,500 residing on the South Field Campus, will be moved to John Hay Hall, the new undergraduate centre on Amsterdam Avenue.

Dr. Welch Professor of Medical History at Johns Hopkins.—Dr. William H. Welch, senior member of the Johns Hopkins Medical Faculties, has been appointed to a full time chair in the history of medicine. This is the first endowed professorship of its kind in America. Dr. Frank J. Goodnow, president of the University, in making public a gift of $200,000 from the General Education Board for the establishment of the new professorship, stated that its purpose was to provide medical students with a cultural background which will make the young physician "more than a technical machine, competent to practice medicine." In order to give his whole time to his new work, Dr. Welch has resigned his position as director of the Johns Hopkins School of Hygiene and Public Health. Dr. William H. Howell, professor of physiology and assistant director of the school, will succeed Dr. Welch as director. Dr. Goodnow stated that Dr. Welch has been chosen to fill the new professorship "because of his intense interest in, and profound knowledge of, the historical background of modern medicine." Dr. Welch is considered to be without a rival in his acquaintance with the early period of American medical history, and the history of medicine in England from 1600 to the present day.

Dr. Charles Perilli to Succeed "Dr. John."—Dr. Charles Perilli has been appointed a trustee of Bellevue Hospital, to succeed his brother, "Dr. John of Little Italy," whose death occurred a few months ago.

Dr. Duel Entertains Building Committee.—Dr. Arthur B. Duel, chairman of the building committee of the New York Academy of Medicine, entertained at dinner on the evening of Monday, November 15th, the members of the building committee and those who have taken part in the erection of the academy's new building on Fifth Avenue and 103rd Street. The dinner was served, from the new and elaborately equipped kitchen, in the collation room on the first floor of the new building.

"The Doctors' Hospital."—Announcement has recently been made that 150 physicians and surgeons of New York are planning to erect a four million dollar hospital, which will provide also hotel accommodations for relatives of patients, on East End Avenue between 87th and 88th Streets, overlooking East River. The new institution, which may be called "the Doctors' Hospital," embodies an effort on the part of many medical men of the city to supplement the present inadequate hospital facilities for private patients.

It was announced that the new hospital will provide not only the best and latest medical, surgical and research facilities, but also the advantages of the most modern hotels.

Uptown Medical Centre Dinner.—Members of the Uptown Medical Centre Association held their second annual dinner on the evening of Tuesday, November 16th, in one of the construction buildings for the new medical centre at Broadway and 168th Street. Dr. C. C. Burlingame, executive secretary of the association, and Mrs. William Vanamee made addresses. Officers for the coming year were elected as follows: president, Mrs. William Vanamee; first vice-president, Colin Woodward; second vice-president, Frank Ritchings; secretary, Dr. Louis T. Wright; treasurer, J. Conrad Scheider. Educational, library, and flower committees were appointed to assist in the hospital work at the centre. It was announced that the association now has more than six hundred members, and that hereafter meetings will be held quarterly.

Appointments at the University of Pennsylvania.—Dr. George S. de Renyi, formerly of Budapest University, has been made assistant professor of anatomy in the School of Medicine of the University of Pennsylvania. Mrs. Carrie K. Bryant has been made assistant professor of microbiology and bacteriopathology in the School of Dentistry. Dr. de Renyi is the fourth new member of the department of anatomy this Fall. Dr. Eliot Round Clark was made professor of anatomy in September, and Dr. Roy G. Williams and Dr. J. C. Sanderson were made instructors. The appointment of Mrs. Bryant gives the School of Dentistry its first woman faculty member. She is the daughter of Dr. Edward C. Kirk, for many years Dean of the School of Dentistry and now professor emeritus of dental pathology and therapeutics.

Dinners Honoring Dr. Rivière.—Dr. A. Joseph Rivière of Paris was guest of honor at a number of social occasions during his recent visit in New York City. Among these was the dinner given by Dr. Victor C. Pedersen, former president of the American Electrotherapeutic Association, at the Delta Kappa Epsilon Club on November 12th. The other guests were Dr. Wendell C. Phillips, Dr. Samuel A. Brown, Dr. Walter L. Niles, Dr. Frederick T. Van Beuren, Jr., Dr. William P. Healy, Dr. Harlow Brooks, Dr. J. Milton Mabbott, Dr. James Pedersen, Dr. William Seaman Bainbridge, and Dr. Harry Eaton Stewart.

On November 9th, Dr. William Seaman Bainbridge entertained at dinner at the Union League Club for Dr. Rivière. Dr. Bainbridge stated in his remarks upon the occasion that the purpose of the dinner was to express the thanks of the Americans who had visited Paris for the hospitality extended, and as a tribute to Dr. Rivière's career in medical research. Among other speakers were Philip Bérier, French Deputy Consul. Johnson Mali, Belgian Consul, representatives of the Franco-American Societies and the International Medical Society, Augustus Thomas, the playwright, and Dr. Herbert Adams Gibbons. More than 150 guests attended the dinner. Dr. Rivière advocated the cooperation of France, Great Britain and the United States in forming an international army to enforce the "socalled League of Nations," declaring that disarmament would follow as a necessary consequence.

Society News and Notes.

Announcement has been made that the former West Side Clinicians have changed their name to the Schuyler District Medical Society. The newly elected officers are, president, Dr. John H. Morrissey; vice-president, Dr. Maximilian Lewson; treasurer, Dr. James V. Ricci; secretary, Dr. John A. Glassburg.

The Pan-American Child Congress, embracing many organizations standing for child welfare, hygiene, education, etc., will be held in Havana, Cuba, February 13-20, 1927. It will meet in six sections: medicine, hygiene, sociology, education, psychology, and legislation. Twelve subjects will be presented in each section. Among topics to be discussed are psychiatric clinics for children, juvenile delinquency, child study laboratories, and the psychology of the preschool child. The Cuban congress will be the first of its kind ever held within convenient distance of the United States.

At the close of a luncheon given recently by Samuel W. Reyburn in New York City, fifty business men pledged their aid in raising the second half of the one million dollar endowment fund of the American Society for the Control of Cancer.

Abstracts from Current Literature

CARDIOVASCULAR DISORDERS

Auricular Fibrillation and Auricular Flutter.—C. W. Curtis Bain (*Clinical Journal,* October 13, 1926) says that both flutter and fibrillation are apt to be accompanied by heart failure, and in the treatment of any particular case, rest in bed, the administration of atropine and morphine, the use of diuretics and the advisability of bleeding would have to be considered. As the treatment of heart failure does not come within the scope of this paper, mention will be made only of those drugs useful in restoring normal rhythm and in controlling the rate. Of the digitalis group the tincture of digitalis or Nativelle granules, if more convenient, by the mouth, and strophanthin intravenously, are useful. The only object in using strophanthin is to obtain an effect quickly, and this is outweighed in most cases by the fact that individuals vary considerably in their reaction to the digitalis group, and so the dose is always doubtful. In all but the most urgent cases, therefore, the slower but more certain method of giving digitalis by mouth is preferable.

In treatment of flutter a dram of the tincture is given daily in three doses. Usually within two days the pulse becomes slower and irregular. The digitalis is continued until the rate falls below 80. If careful watch be now kept, it may be noticed that the pulse has become totally irregular and that the auricles are fibrillating. If digitalis is stopped, normal rhythm will commonly return spontaneously. If it does not return the rate can be controlled with an appropriate dose of the drug.

In the fibrillation of mitral disease with an acute onset and heart failure, a dram or a dram and a half is usually given at once, and is followed up by the same amount daily until the apex rate is below 80. It is then stopped until the rate begins to rise, when half doses are given and continued indefinitely.

Eccleston advocates massive doses of digitalis—six drams of the tincture during the first twenty-four hours. This is unsafe if the patient has had digitalis before, and does not appear to have any advantage over intravenous strophanthin. With the slower method any intolerance to the drug will show itself by bigeminy of the pulse—the digitalis coupling—a diminution of the amount of urine, or by nausea in time to stop the treatment before serious consequences result.

To determine the correct amount to be taken for the future Strickland Goodall uses the following method: The difference between the apex rate and the pulse rate, which always obtains in fibrillation, is due to the fact that some beats fail to open the aortic valves and so reach the wrist. These beats represent wasted energy, and the fewer there are the more economy is there in the work done by the heart. The patient is therefore put to bed and given digitalis until the apex rate is down to below 70. Digitalis is then stopped and the apex and pulse rates taken lying down and standing three times a day until the rate is above 80. With a graph so obtained it can be seen at which rate the apex and pulse most closely approximate. This is the optimum rate for the patient, and the dose is regulated to bring him down to it.

In some patients the supracardiac nervous control still predominates in spite of their fibrillation, and their rates may fluctuate considerably from emotional causes. In these bromide is quite as important in the treatment as digitalis. In the degenerative form with a slow rate digitalis is usually unnecessary. In the toxic and paroxysmal forms it is a matter for serious consideration whether digitalis should be given at all. Most cases have a definite cause, the removal of which will allow the fibrillation to be brought to an end. Digitalis tends to perpetuate fibrillation, and the alternative treatment of quinidin must be borne in mind.

With regard to quinidin therapy there are two schools of thought. One points out that quinidin is a general cardiac poison, that there is never any guarantee of success from its administration, and that where it has succeeded it must be continued in order to prevent a relapse, and will do more harm to the ventricle than can be compensated by the restoration of normal rhythm. The other maintains that fibrillation in itself limits the powers of the heart; that where normal rhythm has been regained with quinidin an increased exercise tolerance is shown by patients still taking the drug compared to what they could do while fibrillating and under digitalis; and that the percentage of failures would be considerably diminished were greater discrimination shown in the selection of cases. For a case to be suitable the fibrillation must not be of long standing and the heart must not be enlarged.

There are two standard methods of administering quinidin, though other modifications are used. One is to give three grains to test for any susceptibility, and after a few hours five grains every two hours until the arranged limit.

In toxic fibrillation, whether due to hyperthyroidism or not, where the source of toxemia can be eliminated by operation it seems reasonable to make an effort to restore normal rhythm after the operation, since the risk of a relapse should not be great. This principle might be applied to certain rheumatic cases with septic tonsils.

In the degenerative type quinidin will seldom be useful. It is not often that cases are seen soon after the onset, and the heart is usually enlarged.

It is in the mechanical type that opinions differ the most. There is little hope at present of diminishing the obstruction to the mitral valve, and no one expects that normal rhythm will persist more than a few years. Those that use the drug claim that during that period the patient can do more, feels better, and is grateful for the improvement in his condition.

In flutter there is always the alternative method of giving digitalis, which may itself bring about the restoration of normal rhythm. It would seem best to give quinidin either at the onset of the attack in the hope of a rapid termination, or else to restrict its use to those occasions when digitalis has failed. One possibility should be borne in mind; since quinidin slows the circus, it lessens the number of impulses passing down to the ventricle. Should these be reduced to about 200 the ventricle may respond to them all. While this is not so severe as in the untreated case, since the rate is slower, there is always an element of danger about it, and it is a sign to stop the drug.

Cardiovascular Symptom Groups in Colitis and Appendicitis.—J. Baumann and P. Martin (*Bulletin de la Société des sciences médicales de Montpellier,* January, 1926) allude, in the first place, to a combination of anemia and low blood pressure resulting from severe colitis, diarrhea of the dysenteric type, amebic dysentery, etc. About seventy per cent. of the cases are due to chronic appendicitis or typhlocolitis. In acute cases, the red cells may drop to two or three millions, while in chronic cases there is a less pronounced anemia which shows aggravation after each recrudescence of the colitis. With the anemia occur lassitude, general depression and apathy, sometimes accompanied by slight jaundice, the urine remaining, however, free of bile, while the anemia yields to treatment of the bowel. Low blood pressure is the most constant manifestation, and may be pronounced; ordinarily the systolic pressure is between 90 and 100 and the diastolic between 50 and 70. The commonest heart symptom is a tendency to syncope; occasionally there are arrhythmias or bradycardia. Loeper, in such anemias, found diminished resistance of the red cells and the presence of a hemolytic agent in the blood serum. This type of disturbance is limited to the relatively recent cases of colon disease, which are still subject to subacute, febrile recrudescences with pain definitely localized in the right side of the large bowel. The stools show, singly or in combination, the colon bacillus, the enterococcus or, less commonly, the perfringens or paratyphoid organisms. The first two of these organisms are now known to have marked hemolytic properties. In contrast to this symptom group attended with nervous disturbances of toxic origin and a tendency to vagotonia is another symptom group featured by high blood pressure and sympatheticotonic manifestations. In this class of cases the patients are elderly and the stools bacteriologically negative. The intestinal lesions are no longer in an active state, the patients retaining as a result of their earlier colitis or appendicitis, merely sequelæ such as relaxation of the intestinal muscular layer and marked dilatation of the cecum. Through cecal stasis there are present putrefaction of the incompletely elaborated food proteins, carbohydrate fermentation, mucous hypersecretion, retention of the products of desquamation from the mucosae, and increased toxicity of the urine, which

is rich in indol, skatol and hydrogen sulphide. The tongue is coated and the breath malodorous. The colitic symptoms differ little from those of the first group, consisting of alternate diarrhea and constipation, and malodorous stools. The pain, however, is less definite, being localized in the nervous plexuses. There are no appreciable recrudescences. The blood pressure varies at different times, the systolic being usually between 160 and 200 and the diastolic between 80 and 90. Dizziness, insomnia, headache and sometimes trophic or cutaneous disturbances are complained of. Colonic lavage by the drop method, administered in four or five "detoxicating" courses at a suitable watering place in each season, is followed by a reduction of blood-pressure. On the other hand, in permanent hypertension due to renal or valvular disease or arteriosclerosis, such treatment is without result.

Coronary Occlusion in General Practice.—Sylvester F. McKeen (*Boston Medical and Surgical Journal,* May 6, 1926) says that coronary occlusion is not a rare disease in general practice. The diagnosis is generally easy, the treatment is plainly indicated, and the prognosis is fairly hopeful. From the viewpoint of treatment, it is highly important to distinguish it from the ordinary angina of effort, from the different acute affections of the upper abdomen, and from those doubtful conditions often described in the newspapers as acute indigestion, ptomaine poisoning, etc. The picture of a typical case should be kept clearly in mind. A man, around middle life is suddenly stricken, perhaps in his sleep, with an intense substernal or epigastric pain that lasts and is not relieved by nitrites or even by ordinary doses of morphine. Signs of grave shock are present, anxious facies, ashy color, clammy skin and rapid, feeble pulse. The heart sounds may be irregular or tic tac in quality. A pericardial rub is sometimes found, and is then pathognomonic. The blood pressure is comparatively low, and, if previous readings are known, a decided drop has evidently occurred. The temperature will probably be found elevated, and the leucocytes are increased. A patient with such symptoms should be put to bed, and made as comfortable as possible with opiates. If the insult to the heart be not too great, he may survive the immediate shock. If he is kept absolutely quiet in bed for at least six weeks, with good nursing the infarct is given the best chance to heal, and the patient the best chance to recover. Moreover, if he has been a sufferer from chronic angina, and hypertension, he may be relieved from both by his coronary occlusion.

Casein of Milk (Curd) as a Diuretic.—A. Jarotzky (*Schweizerische medizinische Wochenschrift,* March 13, 1926) proposes an improvement upon the Karell milk diet in patients with heart disease. Curds are contraindicated in cases with nitrogen retention in the blood. The indications for the casein of milk are the following:

1. In the severe cases of cardiac insufficiency, in which all of the usual cardiac remedies and diuretics have failed to exert a favorable influence. For three days the patient should be given daily 600 to 800 gm. of curds with 100 to 200 gm. of sugar and 100 gm. of sour cream. During these three days the patient must not drink anything and take no fluids at all. Only with this precaution is success possible.
2. The casein of milk (curds) must generally be used in cardiac decompensation in place of milk to a great extent.
3. The use of casein with the exclusion of the administration of all fluids is indicated in all those cases where at the present time only mercurial preparations are being used for diuretic purposes. The casein treatment may also be used in place of calomel.

Relations Between the Concentration of Blood Corpuscles in Venous and Capillary Blood and the Blood Pressure of Diabetic Patients.—Howard F. Root, J. W. Thompson, and R. R. White (*Journal of Laboratory and Clinical Medicine,* February, 1926), compare the relative concentration of corpuscles in capillary and venous blood of twenty-seven diabetic patients in the morning and evening. Variations in arterial tension between these periods do not correlate constantly with any change in the corpuscle concentration. In certain patients, with high diastolic blood pressure, the capillary count (red) was higher than the venous red count at night but lower in the morning. This reversed relation suggests capillary stasis at the end of the day and was more marked in patients with obvious vascular disease. Increases in venous pressure produce the contrary effect; namely, high venous count and low capillary count. The desirability of further study is pointed out. Comparisons of the relative concentration of corpuscles under varying conditions of arterial and venous pressure by means of the hematocrit should be made in cases of rheumatic heart disease, vascular hypertension and edema of cardiovascular origin.

Incipient Valvular Endocarditis as a Clinical Concept.—A discussion is presented by Dr. Nicholas Lukin (*Archives of Pediatrics,* May, 1926) on the pathology and healing process of valvular endocarditis. The possibility of early arrest and limitation of its progress is stated. The author urges the formation of a clinical concept of incipient valvular endocarditis with tonsillitis as a primary etiological factor in order to stop or limit the disease at an incipient stage. The insertion of a special chapter on incipient valvular disease in textbooks is suggested.

SYPHILIS

When May One Speak of the Cure of Syphilis?—Charles Fouquet (*Urologic and Cutaneous Review,* July, 1926) says that there does not exist as yet one single clinical or laboratory sign capable of certifying that an individual once tainted with syphilis is definitely free from his affection. This is not to say that syphilis is not curable. Almost all syphilologists admit that the cure of this disease is possible. Syphilis treated energetically at the prehumoral stage in particular gets well almost always.

If we have not the scientific proof permitting us to deliver to an individual a certificate of the cure of syphilis, we have nevertheless often a group of clinical and laboratory signs which constitute, when they are taken together, an important array of presumptions, permitting the belief that recovery has been obtained. This is the case of those syphilitics in whom the infection dates back many years who have not presented any symptoms for several years, who have had a certain number of negative blood seroreactions during two or three years and who have persistently a normal cerebrospinal fluid. It would appear that one could permit marriage and procreation to such as these.

Mixed Chancre.—Lucien Perin (*Urologic and Cutaneous Review,* July, 1926) applies the term mixed chancre to all of the syphiliticochancroid symbioses and he describes them according to the period of evolution of syphilis at which they manifest themselves, as 1, mixed primary chancre; 2, secondary or secundotertiary mixed chancre, and 3, tertiary mixed chancre.

These different forms have a variable pathogenesis. In primary mixed chancre there is a direct inoculation at the same point with the treponema pallida and the bacillus of Ducrey. This inoculation is simultaneous or successive, but in general it presupposes a terrain previously free from syphilis. The secundotertiary or tertiary mixed chancre is, on the contrary, always conditioned upon a previously syphilitic terrain. Here there is produced a veritable syphilization of the chancroid comparable to that which occurs in syphilitic terrain. Here there is produced a veritable syphilization of the chancroid comparable to that which occurs in syphilitic subjects following trauma or diverse injuries. To this group belongs the papulous soft chancre, ulcerous tertiary chancre, tertiary phagedenic chancre, etc. More rarely the secundary or secundotertiary mixed chancre results from the inoculation of the Ducrey bacillus upon the site of a secondary or secundotertiary lesion in full activity.

When the inoculation with the Ducrey bacillus and the spirochete is simultaneous, on the second day after contagion there appears at the site of inoculation a chancroidal vesicopustule which develops little by little and towards the tenth day gives place to a typical soft chancre. The ulceration is covered with yellow pus, underneath which appears an irregular base with small well like depressions and hemorrhagic islets. The borders are irregular and curve sharply. The base is soft; adenopathy is absent or slightly marked. Sometimes small ulcerations on the back of the penis and an inflammatory adenopathy complete the clinical picture. The Ducrey bacillus may be found in the pus. Toward the twentieth or twenty-fifth day the ulceration changes its character and the syphilitic chancre makes its appearance with the following symptoms: The ulceration becomes more regular, less broken, the floor tends to be raised and to become papulous; the borders are effaced; the purulent secretion diminishes; the base is infiltrated and assumes a hard consistence, sometimes cartilaginous. Some of the glands become hard, without inflammatory character, grouped like satellites around a large ganglion and consti-

tute the type of syphilitic adenopathy. The induration at the base is subject to variation, its intensity varying according to the stage of evolution of the chancroid. In the latent forms of mixed chancre syphilis is frequently unrecognized until the appearance of secondary symptoms.

When the inoculation with Ducrey's bacillus and with the spirochete is successive, two alternatives present themselves: 1, The patient having a syphilitic chancre subjects himself to a new chancroid contamination, or 2, the patient has a simple chancroid and contracts a syphilitic chancre.

In the first stage of the first alternative, the syphilitic chancre shows the usual superficial erosion, without borders, not painful, regular, rounded in form, red at the bottom, not suppurating, indurated base accompanied by a characteristic hard, indolent adenopathy. The spirochete finding and even the Wassermann blood reaction may be positive. The chancre shows changes from the second day: on the regular bottom appear little well shaped depressions, small ecchymotic spots appear, the borders grow in all directions and the ulceration continues more or less deeply, irregularly cut out. The base of the ulcer suppurates and becomes painful. The glands assume an inflammatory character, sometimes even suppurate. Lymphangitic abcesses develop and give place to chancroidal ulcerations after spontaneous rupture. Autoinoculation is positive with the pus of the ulceration or bubo or lymphangitic abscesses.

The second alternative is less common because the chancroid is generally painful, preventing intercourse. The resultant mixed chancre differs in no way from that of simultaneous inoculation except in the longer lapse of time between the beginning of the chancroid and the appearance of the chancre.

The term mixed bubo is applied to the association of syphilitic bubo and chancroid bubo. The former is constant with mixed chancre, the latter is observed less often.

The diagnosis has two essential points: the recognition of syphilis at the commencement of its appearance, and the recognition of the chancroid. The diagnosis of syphilis is the most important. In fact, every chancroid should be suspected and in the presence of the most characteristic chancroid one should always think of the possibility of the appearance later of a syphilitic chancre. The sources of error are rare: 1, the soft nodular chancroid which accompanies a nodular induration; 2, therapeutic indurations produced by cauterizations and topical remedies. The diagnosis of syphilis is made from the findings of a positive spirochete or the Wassermann reaction (later). On the other hand, one should suspect the coexistence of chancroid in the presence of every syphilitic chancre with an ulcerative or phagedenic tendency, and in the presence of every syphilitic chancre accompanied by inflammatory adenopathy or lymphangitic abscess. Repeated examinations for the Ducrey bacillus may be necessary. Where this bacillus cannot be found, autoinoculation may be tried.

The treatment of the syphilis is that usually practiced in uncomplicated cases. Two reservations should be followed in the treatment of the chancroid: Not to use any process of cauterization susceptible of producing artificial induration; not to use any local treatment preventing the direct examination for the spirochete.

Some of the Medicosociological Aspects of Syphilis.—Arthur M. Barnett (*Urologic and Cutaneous Review*, July, 1926) suggests the following procedure in the handling of early cases of syphilis, namely:

1. That all lesions of the external genitals should be regarded as syphilitic until proved otherwise.

2. That no physician however skilled should regard himself competent to make a clinical differential diagnosis between chancre and chancroid by observation alone.

3. That all lesions of the external genitals should be subjected to repeated dark field illumination with the aim of isolating the infecting organism; failing to do so, the Kahn microscopic test should be made with serum from the lesion, as well as a Wassermann test with scrapings and serum from the lesion.

4. That after the appearance of the lesion a Wassermann blood test should be made every three or four days for the first three weeks, and once a week for the next two months, before the patient is dismissed.

5. That all patients presenting lesions of the external genitals should be hospitalized until a definite diagnosis is made, and in the event of a diagnosis of syphilis, at least three doses of arsphenamin administered, thus rendering them sufficiently noninfectious to permit them to safely mingle in society, with instructions to continue treatment in the out patient department of the hospital or to place themselves under the care of private physicians.

6. That any physician observing lesions of the external genitals owes it to his patients to make an early diagnosis, and in the event of his not being equipped to do so he should refer such patients to an institution or some private physician equipped to do this work.

Peroral Novasurol Therapy.—The methods of administering novasurol as practiced heretofore have been found to be unsatisfactory therapeutically and were not well borne by the patient. Only after novasurol powder was given in hardened gelatine sapsule were any therapeutic effects observable in cardiac dropsy. With this method the recurrence of edema and the development of hydrops are avoided. Paul Saxl (*Wiener klinische Wochenschrift*, July 8, 1926) administers the novasurol in gelatin capsules, each containing 0.2 gm. novasurol. As a rule, these capsules are well borne; there may be some gastric disturbance two hours after taking it, but this is only transitory and no serious disturbances of any kind were observed. The capsule is usually given after breakfast. The usual oral hygiene is instituted.

The usual novasurol injections may be given for years, but as soon as these are discontinued the patient always goes into a very serious condition. The peroral method of administration, however, makes it possible to allow intervals of treatment and also provides a more marked dehydration; it prevents the recurrence of the accumulation of water in the tissues in entirely or almost completely dehydrated cases of hydrops. The beneficial effect is noticeable particularly in cases of heart disease, in which cases, naturally, the activity of the heart must be maintained at its maximum efficiency by means of digitalization.

The contraindications include renal insufficiency, excessive hypertension, anemia, cachexia, fever and diarrhea.

Syphilis of the Nervous System.—W. H. Mayer (*International Journal of Medicine and Surgery*, 39:4) classifies the types of neurosyphilis as follows: 1. The milder manifestations of neurosyphilis, such as the ocular palsies and coincident visual disturbances; 2, the convulsive type; 3, the hemiplegic type; 4, tabes dorsalis; 5, the paretic type, and 6, asymptomatic cases with positive laboratory findings.

Of the treatment of these various types he says that he cannot urge too strongly against the treating of a positive Wassermann instead of the patient, for it must be remembered that basically the Wassermann is the indication of the immunity reaction of the patient. Salvarsan is itself an intense nerve poison and its administration should be guarded where any evidence of acute inflammation of the meninges is present.

Many cases of neurosyphilis do well on small repeated doses of salvarsan, especially those with mild tabetic pains or with radicular symptoms, but the author believes that salvarsan itself renders the individual noninfectious, but it does not cure syphilis.

Bone Syphilis.—Frederick H. Dillingham and Lawrence K. McCafferty (*American Journal of Syphilis*, July, 1926) state that one may conclude that when syphilis of the bone exists for any length of time we not only get periostitis, but at the same time we frequently get various phases of bone pathology, such as sclerosis, rarefaction and osteomyelitis. It is only at the beginning of bone syphilis that we see the wavy, irregular line of the periosteum which almost always means syphilitic periostitis. We see this picture so frequently that one may lose sight of the fact that syphilis may also cause other definite lesions. We should not wait until the bone shows marked involvement, but should be on the lookout for syphilis at the first sign of nocturnal pain. We should not treat too lightly the "aches and pains" of middle life but should attempt to assign a definite cause rather than to classify them all under the term neurasthenia, rheumatoid, etc. A roentgenogram should always follow a negative Wassermann in persistent nocturnal pains whether or not the history is suggestive of syphilis. As is commonly known, the Wassermann reaction is not always positive in late syphilis. The roentgenologist may not be able always to definitely differentiate bone syphilis from tuberculosis and other diseases of the bone, but he can frequently aid us in arriving at a tentative diagnosis. At times it may be necessary to resort to the therapeutic test, but this is infrequent.

DIABETES

Effect of Exercise on Insulin Action in Diabetes.—R. D. Lawrence (*British Medical Journal,* April 10, 1926) found that the immediate effect of exercise in increasing the fall of blood sugar caused by insulin is very great. This occurs only during the maximum period of insulin activity—that is, from one to four hours after the injection. Severe and prolonged exercise and half the dose of insulin may produce as great a fall of blood sugar as the usual dose without exercise.

Besides the immediate fall of blood sugar, exercise causes insulin to burn more carbohydrate than usual and to deplete the body stores of carbohydrate. For this reason the dose of insulin succeeding exercise has often an unusually powerful effect in producing hypoglycemia.

If the diet is kept constant, an increase of exercise over days and weeks allows a reduction of insulin to be made. This is one of the reasons why the dose of insulin can often be reduced early in the treatment when patients leave the hospital and adopt a more active existence. If this reduction is not made symptoms of hypoglycemia appear. When the added exercise is omitted the insulin must be raised again.

It should be the object of all treatment to enable a diabetic to lead a normal and varied life, and to forget all about his disease except at meal times. Accordingly allowances must be made for the changing conditions that may arise in life. Patients should and do easily learn to reduce their insulin before unaccustomed exercise or activity, or they must take vigorous exercise only at times when the effect of their injections has worn off. Even after exercise, when the usual carbohydrate stores have been partially depleted, it is usually advisable to reduce the next dose of insulin. If exercise is increased over days or weeks it is obviously more physiological to increase the diet instead of, or as well as, reducing the insulin. The increased calorific output must ultimately be balanced by an increased intake, otherwise weight and energy will be lost. A diet which supplies thirty calories per kilogram of body weight may be a sufficient "maintenance" diet for a sedentary life, but forty calories may not be too much merely to maintain the requirements of a more active existence.

Biochemical Rehabilitation of Diabetics.—W. J. Mayo (*Annals of Surgery,* 84:2) says that progress in the surgical treatment of patients with diabetes has come, not so much through improvement in technic, as in the preoperative care of the patient, in the attention to such small matters as the care of the feet, the prevention of skin infections, and in the intelligent use of diet, insulin and glucose.

The test for the amount of sugar in the urine as a guide to the severity of diabetes has largely given way to a test for sugar in the blood. Sugar in the blood is a threshold substance. The threshold varies greatly in height in different persons. When the sugar exceeds a certain level, so to speak, it flows over the top and appears in the urnie. A person with a low sugar threshold may have glycosuria after eating an unusual amount of carbohydrates, such as candy, and yet not become afflicted with diabetes. Another person with high sugar threshold may have no sugar in the urine, but an excess in the blood, which in cases of slight infection may cause serious disturbances. Even study of the sugar in the blood may fail to tell the whole story. Sugar is stored in the liver and other tissues as glycogen, which is merely a condensation product of glucose.

If pancreatitis accompanies infection of the gallbladder, it does not take the form of atrophy of the pancreas and of the islands of Langerhans, rather characteristic of diabetes. On the contrary, the changes in the pancreas, as a result of biliary infections are usually of the type called chronic pancreatitis, enlargement and thickening. Removal of the infected gallbladder in the presence of chronic pancreatitis may be followed by improvement in the diabetes, but such a favorable result is not obtained with sufficient frequency to justify operating, in the hope of curing the diabetes, on a gallbladder suspected of being diseased. At least it is a comfort to know that diabetes is not necessarily a contraindication to an operation for definite disease of the gallbladder.

It has been a common experience in cases of diabetes, that when there is arteriosclerotic gangrene of the lower extremities, which necessitates amputation of part of the limb, great improvement in the general condition of the patient with a reduction in the symptoms of diabetes may take place after the amputation. Joslin is wise in his advice to amputate the leg above the knee in cases of the acute, florid type of diabetic gangrene when there is discoloration of the entire foot and ankle without a line of demarcation, and high temperature. He emphasizes the fact that care of the feet, next to a proper diatetic regimen, is the most important measure in the treatment of diabetes. A patient with diabetes should wear several pairs of shoes in succession. The trimming of corns and calluses should be regarded as a serious operation, to be done under antiseptic precautions, in the morning rather than at night, so that all swelling and edema in the muscles about the foot from the day's usage will have disappeared.

The use of the actual cautery to destroy carbuncles is extraordinarily efficacious. It has been used in the clinic successfully for many years for all forms of carbuncles, both in the patient with diabetes and the patient without diabetes. The dark red heat of the soldering iron is best, and with it the entire area of the carbuncle is converted into an eschar. The eschar is left without a dressing, and the dry treatment for burns is applied. If necessary, an electric fan is used to keep the surface dry, and dry powdered boric acid may be rubbed in to absorb moisture. When the slough begins to separate, the usual applications of antiseptic wet dressings are made. Astonishing results are seen in cases of severe carbuncle. The patient suffering with pain and high temperature, within a few hours after the cautery treatment is quite comfortable and up and about with normal temperature.

Interpretation of Sugar Tolerance Tests; the Common Occurrence of Renal Glycosuria.—Herman O. Mosenthal (*Medical Clinics of North America,* November, 1925) proposes the following classification of blood sugar curves, based on the ideas that the normal fasting blood sugar should be 120 mg. or less, that after the administration of 100 gm. of glucose the blood sugar should not rise above 160 and that the blood sugar should return to 120 mg. or less within two hours; any curve in which the blood sugar rises above 160 mg. is termed a "high curve"; any curve which lasts longer than two hours is designated as "prolonged." Those curves are regarded as "low" in which at no time during the period of observation the blood sugar rises above 120 mg. per 100 c. c. Such low curves exist in normals and in pathological conditions are helpful in diagnosis, as in hypopituitarism.

Every case of diabetes mellitus exhibits a high prolonged curve, though there are very many conditions in which a high prolonged curve is not associated with diabetes mellitus. Many persons in whom intermittent glycosuria occurs, that is not readily diagnosed as diabetes mellitus, do not suffer with this disease; among such cases an extraordinary number of instances of renal glycosuria is found.

Renal glycosuria may be an acquired functional disturbance; the author's series of observations bears out those who believe that renal glycosuria is a harmless anomaly and bears no relation to diabetes mellitus.

Uremic Death in Diabetic Coma.—P. Merklen, M. Wolf and P. Bicart (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris,* March 11, 1926), describe a case of diabetic coma in which insulin reduced the blood sugar from 5.3 to 1.2 grams, caused the glycosuria to disappear and greatly diminished the acidosis; meanwhile, however, the output of urine dropped, albuminuria increased, with many casts in the urinary sediment, and the blood urea rose to one gram and later to 1.3 grams. The general condition grew worse, and the patient succumbed with rapidly progressive manifestations of renal failure, in the face of the improvement in the diabetic symptoms. The case illustrated the fact that some cases of diabetic coma are not saved by insulin, but die of a superadded uremia. Hence the unfavorable prognosis emphasized by some writers for cases of diabetic coma in which the blood urea is high. Death occurs in these cases even before the blood urea has reached two grams. With Ambard and others, the authors account for the unexpected deaths in that acidosis is capable of rapidly inducing lesions of the kidneys, which persist after disappearance of the acidosis. The prognosis of diabetic coma treated with insulin depends not only on the course of the blood sugar and ketone bodies but also on the renal condition as reflected in oliguria and anuria, progressive albuminuria, casts and elevation of blood urea. The latter should be estimated at short intervals; if it is rising, the prognosis is bad and if falling, more favorable.

PROCEDURE UNDER NORTH DAKOTA STATUTE AS TO REVOCATION OF LICENSES

The North Dakota Supreme Court holds, In re Shortridge, 207 N. W. 442, that a proceeding before the state board of medical examiners, upon a complaint against a physician for the purpose of revoking his license, is administrative, not judicial. The state may prescribe the conditions under which a person may be permitted to hold himself out to the public as a qualified physician and surgeon; it may give a board the power to grant and revoke licenses to practice medicine on grounds prescribed by the law. Ordinarily the courts will not interfere with the action of such a board except in cases where it has acted arbitrarily, or threatens to act under statutes purporting to give arbitrary power to deprive a person of the valuable right to practice his profession.

It was held that the licensee was not entitled to a new trial in the district court, with the right to introduce new evidence, the North Dakota statute dealing with the subject of revocation of licenses, Comp. St. 1913, §468, clearly contemplating that the trial in the district court shall be upon the record transmitted by the board of medical examiners and the evidence upon which that tribunal based its findings and conclusions. There is no suggestion in the statute that there shall be a new trial in the district court, with the right to offer new evidence, or, perhaps, raise new issues. The statute simply allows an appeal upon the record as made by and before the board. Manifestly, the right of review thus accorded is amply sufficient to protect the physician's right to due process, and to ensure against arbitrary action by the board depriving him of substantial legal rights.

BURDEN OF PROOF OF AVAILABILITY OF X RAY APPARATUS

The Wyoming Supreme Court holds, Wright v. Conway, 242 Pac. 1107, that, in a malpratice case, the facts that an x ray apparatus was available and used four weeks after the diagnosis and commencement of the treatment of a broken femur did not justify an inference that the same instrument was available at all times before that, including the time of the diagnosis and beginning of the treatment, especially in view of the fact that if such a machine was available the plaintiff was in a situation at the time of the trial to have shown the fact by his expert witness. To have thrown the burden upon the defendant of showing that he could not secure an x ray at the time when it was charged to have been negligence not to use it would have placed upon him the burden of proving that he was not negligent, which is not the rule in malpractice cases. The court refused to hold, without evidence, that x ray instruments are so commonly used by physicians in communities like Cheyenne, Wyo., where the defendant practiced, as to justify an inference of availability on that ground alone, especially as defendant had testified that he could not get a machine and could not take the patient to one. There was, moreover, insufficiency of proof of any causal connection between such failure to use x ray and the subsequent injury for which damages were claimed.

PROCEDURE UNDER CALIFORNIA MEDICAL PRACTICE ACT, SECTION 14

The California District Court of Appeal, First District, holds, Grisso v. Board of Medical Examiners, 242 Pac. 912, that the provision of section 14 of the California Medical Practice Act, as amended by St. 1921, p. 1012, for an appeal from an order of the state board of medical examiners revoking a physician's license, to the superior court of the county where the revocation was made, is unconstitutional, and that certiorari or writ of review is the proper remedy. On application for such a writ of review the court need only determine whether the state board acted according to section 14, as amended, which makes provision for revocation by the board, outlines the procedure and sets forth the causes for revocations whether the board had jurisdiction over the defendant, and whether a hearing was had and evidence supporting the charge was adduced at that hearing. The board's power under this section has been repeatedly upheld in California courts. The filing by a physician with a county clerk of a certificate provided for by section 2466, California Civil Code, stating that he was the sole owner of "Bohannon Cancer Institute," and was doing business under that name was held to be a violation of section 14, subd. 8, as amended, in which the use by a physician and surgeon of a fictitious name, or any name other than his own, is declared unprofessional conduct, so as to authorize the revocation of his license.

CHARITABLE HOSPITALS DUTY IN SELECTION OF ITS AGENTS

The Washington Supreme Court holds, Tribble v. Missionary Sisters of the Sacred Heart, 242 Pac. 372, that merely because a hospital receives or exacts compensation from those desiring its privileges to the extent of their ability to pay does not necessarily deprive the institution of its character as a charitable one.

After an operation in such a hospital, a patient, while still under the influence of an anesthetic, was taken to his room and placed in bed. His attendant or attendants neglected to remove an aluminum bottle of hot water which had been placed in the bed, and which in a short time severely burned him. He sued the hospital, alleging negligence in its care of him and in the selection and retention of the person assigned to take care of him. It was held that a charitable hospital is liable for injuries arising from failure to exercise due care in the selection of its servants. Whether the hospital was negligent in the employment of a probationer nurse who, it was claimed, caused the injury, was held, under the evidence, to be a question for the jury.

OPINION EVIDENCE AS TO MENTAL CAPACITY TO EXECUTE WILL

In a will contest case a medical witness for the contestants was allowed over objection to answer a question as to whether the testator had mental capacity to understand or carry on a business transaction. The Texas Court of Civil Appeals holds, Curtis v. Adams, 275 S. W. 206, that the objection should have been sustained. The court said, in part: "In the trial of cases of this character it is permissible for a witness, who is qualified, to state whether in his opinion the mind of the testator is sound or unsound; but he cannot give his opinion as to the mental capacity of the testator to perform the act then under investigation. When stripped of its surplus verbiage, the question asked of Dr. Millan was: Did the testator have mental capacity to conduct a business transaction? The only business transaction the parties then had in mind, and to which this question could have any reference, was the execution of the will in controversy. The answer was, in effect, the opinion of the witness on the very issue which the jury or the court was called upon to decide."

OPINION EVIDENCE AS TO CAUSE OF INJURY

The Missouri Court of Appeals holds, Duvall v. Brooklyn Cooperage Co., 275 S. W. 586, that any hypothetical questions to a doctor should not call for his opinion as to the possibility of an injury resulting from certain causes, but should require him to state if, in his opinion, such injuries would result from such causes to a reasonable degree of certainty.

Unrecognized Nasal Sinusitis*

IRVING WILSON VOORHEES, M.S., M.D.
New York

This little paper is not written for the rhinologist of experience, but for that very large group of physicians in other fields who are unfamiliar with important facts here set down.

Every sinus disease begins as a complication of purulent rhinitis. First, there is the socalled cold in the head with sneezing and watery discharge. Two or three days later the watery discharge becomes purulent. If not copious in amount, pus is probably being formed in the Schneiderian membrane covering the septum, turbinates and general nasal interior. This condition lasts about one week only and the cold clears without "going down on the chest," into the ears or into the nasal sinuses. In other words, a simple disease has been well taken care of by the natural defenses of the body, and therefore has been quickly thrown off. Such a condition is properly described as an acute purulent rhinitis simplex. Not much attention is paid to it by the patient; the physician, if consulted, prescribes rhinitis tablets, a cathartic, and possibly an alkaline wash, and the trifling disease is speedily forgotten. That is a lucky outcome for the patient who does not realize that he has escaped abscesses in the middle ears, mastoiditis with possible complications in the brain or venous sinuses, and lung infection such as pneumonia or tuberculosis. In fact, many persons seldom or never connect serious diseases with a socalled cold, but this condition is primordial in illnesses that persist throughout months or years and end in a fatality; for example, brain abscess or pulmonary tuberculosis.

Every chronic disease was at some time acute. Chronicity represents merely the inability or failure of Nature to heal disease within a limited time of days or weeks. Anatomical construction may prevent Nature from utilizing her factors of safety. Then there is to be reckoned with, of course, the virulence and viability of the microorganisms which are the exciting cause of the malady.

If one studies carefully the anatomical configuration of the nasal sinuses it is surprising that, once infected, they should ever become normal again; and yet the tendency to healing is so potent that recovery is the rule and chronicity is the exception.

All of these head cavities have small openings or communications with the nasal fossæ, but they are disadvantageously placed. The frontal sinus, the antrum, and the anterior ethmoid cells of each side open near each other in the middle meatus beneath the middle turbinate. The posterior ethmoids and sphenoid open into the recessus sphenoethmoidalis far back and high up so that secretions from them must flow into the postnasal space. The antrum opening is small and high up in the outer wall of the nose and drainage must take place uphill, or when the head is flat upon a pillow if at all. Curiously enough the frontals, which of all sinuses are best located for gravity drainage, have a nasofrontal duct or groove which guides their secretions directly into the antrum opening, or passing that by, into the postnasal space. Moreover, these openings, once they become blocked by swelling or thickening of the mucous membrane, are likely to remain closed, and then the secretions within the cavities are bottled up and we have to deal with a closed empyema which is fairly inaccessible even to the special student or worker in these regions. No mechanic of any ability would build such an awkward, stupid, interrelated set of chambers such as these are. He would certainly provide against accidents and eventualities which might be limited at any rate even if unpreventable.

Acute sinusitis is quite easily diagnosed. There is always a severe cold in the head lasting a week or so, followed by a period during which profuse yellowish or greenish discharge is brought back out of the pharynx or blown forward into a handkerchief. Along with these evidences there is headache of a peculiar type, mental depression, loss of appetite, and stuffiness in the ears. Elevation of temperature is not the rule, although it may rise a half or one degree above normal.

If the frontal sinuses are involved, headache comes on at a rather definite hour each morning, and leaves at about the same time each afternoon. This is thought by many authorities to be pathognomonic of frontal sinus disease. There is tenderness at the inner canthus below the supraorbital margin, and percussion over the frontal bone may elicit pain. One must remember, however, that sometimes in antrum disease, pain is referred to the frontal region and is not at all located in the face—a fact well emphasized by Ross Hall Skillern of Philadelphia. In every case of suspected sinus disease the teeth should be carefully

Copyright, 1926, by A. R. Elliott Publishing Company.

studied, as a carious tooth may lead to a mistaken diagnosis of sinus or ear disease and vice versa.

As mentioned, many cases of acute sinusitis subside spontaneously or after some simple treatment such as spraying or irrigating, but in this article I wish to stress the importance of recognizing the subacute, latent, or chronic infections of the paranasal cavities.

Chronic sinusitis is very frequently overlooked. Even the rhinologist who is thinking only of nasal insufficiency (obstruction) may fail to keep the sinuses in mind while making an examination. In many of these cases there is a deviated septum and hypertrophied turbinates. Correction of either or both fails to relieve the major symptoms, and the patient condemns nasal surgery as a vain and worthless procedure.

Practically all chronic sinus cases have a hypersecretion of a mucopurulent nature which falls into the postnasal space and follows the postpharyngeal wall to the upper part of the larynx, infecting it and passing on into the esophagus. There results a chronic laryngitis with frequent desire to clear the throat—the "A-hem" sound being characteristic of the effect made to shake secretion loose from the cords. The patient comes in complaining of his throat. There is dryness or the feeling of a lump or ball, or hoarseness which comes and goes according to the presence or absence of postnasal secretion. Nasal symptoms may not be described, but careful questioning will elicit them. Such patients are exceedingly susceptible to colds because they are "carriers" of bacteria and are so sensitized that a slight chilling, damp feet or a draft will produce immediate symptoms of rhinitis. Examination of the nose shows fluid pus or dried pus—crusts—and a scaly looking mucous membrane. The throat is dry and may show a true "pharyngitis sicca." In fact I have never seen the latter unless in connection with a sinusitis which is always present.

When nasal polypi are seen there is probably chronic disease of one or more sinuses. These growths are found chiefly in the middle meatus and originate in the ethmoid labyrinth or in the antrum. The old fashioned way of treatment was removal of the polypi with a cold wire loop without further inquiry into their deep origin. This gave some relief to nasal breathing, but the locus from which polyps grew was seldom touched. In recent years an attempt is made to exenterate the entire polyp bearing area. Of course, this is impossible in some cases, and small polypi will continue to grow out from inaccessible regions, but they can be kept down by cautery and removal so that the patient is very comfortable.

Chronic purulent infection in the nasal sinuses may cause chronic tonsillitis with fluid pus or cheesy deposits, tracheobronchitis and gastrointestinal disorders from swallowed pus. It is, therefore, a good rule to remove such tonsils before undertaking any sinus operation, as an acute tonsillitis not infrequently develops sharply upon any intranasal surgery—even cauterization of an inferior turbinate may light up a smouldering tonsil infection into an acute follicular tonsillitis.

One need not go into the matter of focal infection to emphasize the fact that chronic nasal sinusitis may be a potent and yet undiscovered source of bacterial invasion of the general system. To my way of thinking it is usually more important than tooth infection, and may antedate and supersede either the teeth or tonsils in the search for bacterial foci.

CONCLUSIONS

This paper is a failure if I have not made clear the following:

1. Many cases of sinusitis are masquerading under the word "catarrh."

2. Headache and postnasal discharge are pathognomonic of sinus disease.

3. Nasal obstruction is frequently but not always associated with sinusitis.

4. There are many missed cases which ought to be easily diagnosed.

5. Definite diagnosis is established from a good history, careful clinical examination, irrigation and aspiration, and, finally, x ray pictures.

6. Acute sinusitis recovers usually through relatively simple treatment; chronic sinusitis through operation and prolonged treatment.

Blood Pressure and Its Pathological Changes

JULIUS FERBER, M.D.
New York

The advent of modern instruments of precision was followed by the auscultatory method for determining blood pressure suggested by Korotkow in 1905. Systolic as well as diastolic pressures can now be estimated clinically, with approximate accuracy.

Blood pressure is a term used to designate the measurable pressure exerted by the blood at any given point in the circulatory apparatus at any given moment. We may thus speak of intrauricular, intraventricular, arterial, capillary or venous pressure.

The arterial blood pressure is the result of a double effect. 1. The amount of blood thrown by the heart into the arterial system. 2. The amount of blood leaving the arterial system through the arterioles and capillaries (peripheral resistance). The amount of blood ejected by the heart will in its turn depend upon a, the force with which the heart contracts; b, the amount of blood contained in the heart; c, the number of heart beats a minute. A change in any of these factors would cause an alteration in the blood pressure provided there is no compensatory factor to nullify this effect.

The blood pressure throughout the vascular system varies not only with the phase of the heart contraction, whether systole or diastole, but also with the point at which it is taken depending on the size of the vessel and its elevation with regard to the heart (effect of gravity). The highest pressure is naturally in the aorta, and as we proceed with the brachial and radial arteries we find a gradual decline until we reach the capillaries where a sudden decline in pressure takes place. In the prone position the lateral pressure throughout the aorta is almost constant; in the standing position, however, the pressure at the lower end of the aorta is higher than that at the arch by the weight of the column of blood; approximately two mm. mercury per inch. The pressure in the veins depends largely upon the position of the body. In the upright position the pressure near the heart may be almost nil, varying of course with the phase of respiration, but as we go down the pressure increases about two mm. for each inch, due to the weight of the column of blood.

The resistance offered to the flow of blood at the periphery, namely the arterioles and capillaries, is a very important factor in determining the arterial tension. If the tone of these vessels is decreased and their size diminished the outflow of blood from the arteries into the veins is decreased, the pressure in the aorta is increased and the heart must contract with greater force in order to empty its content into the aorta. The pressure in the arterial system rises until it is high enough to overcome this resistance and allow for the outflow of as much blood as is thrown into the aorta with each heart beat.

The regulation of the tone of the arterioles and capillaries is brought about by the vasomotor nervous system. The vasomotor system consists of two parts, the vasoconstrictor and the vasodilator system. It has been claimed that chemical substances produced in the body may play a part in the regulation of the vascular tone. Gaskell has shown that acids in low concentration acting locally cause vasodilatation. This led to the suggestion that lactic and carbonic acids generated during muscular activity may have a local action on the bloodvessels causing dilatation of the arterioles and an increased blood flow. The central effect of these acids on the vasomotor centres, however, is to cause a contraction of the bloodvessels and a rise in blood pressure.

The constant secretion of epinephrin by the adrenals has been suggested as a factor in the maintenance of vascular tone and in the regulation of blood pressure. Cannon has shown that in cats after excitement there is an increased secretion of epinephrin. Under certain conditions such as in the case of excitement or sudden exertion the adrenals are stimulated. These organs respond with an increased secretion, epinephrin, which causes a rise in the arterial blood pressure. This will occur in all cases where the organism is called upon suddenly for an increased physical or mental effort. Under normal conditions, however, it is doubtful whether the adrenals play any important part as regulators of the vascular tonus. Hoskin and McClure have found that the amount of epinephrin that would be necessary in the circulation, in order to affect the blood pressure, would cause suppression of intestinal peristalsis. Moreover, the demonstration of minute quantities of adrenalin in the blood stream is extremely difficult, and the various tests employed are open to criticism. Posterior pituitary extract when injected intravenously causes a rise of blood pressure. The maximum rise in pressure may be as great as that following epinephrin, but the site of action is a different one. Epinephrin acts on the myoneural junction while pituitrin acts directly on the muscle of the arterial wall.

Subcutaneous or even intramuscular injections of pituitrin have as a rule little or no effect on blood pressure. The same is in the main true of epinephrin although deep intramuscular injection of the latter is more apt to cause an estimable rise of pressure.

Extracts of different organs such as pancreas, testis, ovary, thymus, brain, etc., produce on injection a fall of blood pressure. This fall is probably due to a substance called cholin. The fact that these substances have been extracted chemically from the different organs is of course no proof that they are normally secreted into the circulation or that they are under ordinary circumstances regulators of blood pressure.

BLOOD PRESSURE WAVES

If the blood pressure curve is recorded by suitable apparatus for any length of time three distinct orders of pressure oscillations can be observed. The first, the shortest wave, is cardiac and corresponds to the heart beat. It is caused by the difference in tension between the systolic and diastolic phases of the heart cycle. Next comes a longer wave known as the respiratory wave which is due to the combined effect of the changes in the pulmonary vessels, the changes in the vasomotor and cardiac inhibitory centres, and to some extent to the variations in thoracic and intra-abdominal pressures. Finally, there are still longer waves, the socalled oscillations of the third order. These are due mainly to rhythmic changes in the activity of the vasoconstrictor centre, and are apparently responsible for the blood pressure variations found in normal individuals.

PHYSIOLOGICAL BLOOD PRESSURE VARIATIONS

When blood pressure measurements are taken at the brachial artery with the individual in the sitting posture, the average systolic pressure for men is according to Woley 127 mm. mercury, for women 120 mm., and for children between six to twelve years of age 112 mm.

After the middle period of life the systolic pressure shows a tendency to rise. The increased pressure may in a certain sense be considered physiological as it is apparently compensatory in nature, but it should not exceed certain limits if not complicated by cardiovascular disease. A persistent pressure above 150 mm. Hg. during any period of life is pathological.

The blood pressure is lowest when a person is asleep, and gradually rises near the end of the sleep. Disturbing dreams may raise the pressure considerably. It is a known fact that unpleasant dreams may cause a patient to wake up suddenly at night with an attack of angina pectoris.

After a meal the blood pressure is raised. Mental excitement of whatever nature, even the novelty of having blood pressure measured for the first time, raises the blood pressure in normal individuals. All these variations affect mainly the systolic pressure, the diastolic pressure varies but little.

PATHOLOGICAL BLOOD PRESSURE CHANGES

The pathological changes in blood pressure are manifested either in a lasting increase known as hypertension or a lasting decrease known as hypotension.

Chronic hypertension may be associated with well established pathological conditions such as arteriosclerosis, nephritis, endocrine disturbances, or it may be the only discernible sign of abnormality. When appearing independent of other known diseased conditions it is designated as essential hypertension.

CLASSIFICATION OF HYPERTENSION CASES

The hypertension cases can be divided into three groups. 1. Those with a high systolic and a high diastolic pressure. 2. Those with a high systolic and a comparatively normal diastolic pressure. 3. Those with a high systolic and a low diastolic pressure. Cases belonging to the last group are conspicuously those of aortic regurgitation. Cases of the first group have but little elevation of pulse pressure, while cases in groups two and three give a high pulse pressure. The pulse pressure of cases in group three may exceed the diastolic pressure. If we try to arrange the different cases of hypertension into these several groups we find that those cases who show the same disease entity differ as to amplitude of the pulse pressure. In a series of fifty cases in our clinic there were eleven cases of nephritis associated with hypertension, and of these three showed a normal diastolic pressure while the others had a high diastolic pressure. Obviously, the exact mechanism in the production of the hypertension must vary in these cases. Our inability to evaluate the different factors responsible for the increase in blood pressure in each individual case, precludes a classification based upon the dynamics of the cardiovascular system.

Clinically the cases of hypertension may be classified for convenience into:

Functional.—This class includes cases of increased blood pressure due to excitement, exertion, pain reflexes, etc.

Organic.—Here belong, a, cases with heart disease, notably aortic insufficiency; b, cases with vascular disease, namely, arteriosclerosis and syphilitic involvement of the vascular system; c, cases with blood changes, namely, polycythemia; d, cases with kidney disease.

Essential hypertension.—Those cases with a permanently increased blood pressure due to unknown causes and associated with no demonstrable pathologic changes in the organism.

Toxic.—Here belong cases of asphyxia, cerebral anemia due to increased intracranial pressure, eclampsia, acute uremia, exophthalmic goitre and other endocrine disturbances, nicotine poisoning, etc.

THE EFFECT OF HIGH BLOOD PRESSURE UPON THE ORGANS OF THE BODY

A permanent increase of pressure necessarily implies a continued increase of ventricular force ejecting the blood under higher pressure than normal. The volume outflow, however, is not always increased, and in fact may be diminished. If the nutrition of the heart is good, this increased effort leads eventually to hypertrophy mainly of the left ventricle. The enlargement of the heart may become very marked, and depends on the ability of the heart muscle to respond to the demand for increased work and the amount of work actually done.

Associated with continued high blood pressure there are in the majority of cases changes in the vessel wall. The aorta and large vessels are dilated and their walls are thick, fibrous, and show a loss of elasticity. There are patches of arteriosclerosis. The smaller arteries and arterioles show different degrees of fibrous thickening and arteriosclerotic changes depending upon the type of the case. The glomeruli and vessels of the kidneys are almost always affected.

There is a difference of opinion as to the cause of these heart and vessel changes. Some authorities consider these the result of the high blood pressure, while others attribute them to the direct effect of the toxins which cause the arterial spasm and hypertension. In some cases arteriosclerotic changes undoubtedly result from toxins of acute infections or syphilis, and marked vascular changes may be discerned before any evident rise in blood pressure. Hypertension is not always associated with arteriosclerosis. According to Norris "about one third of all cases of well marked peripheral arteriosclerosis have normal blood pressures. In the remaining two thirds the pressure is variably increased, depending mainly upon the degree of renal involvements." In a series of twenty-nine cases of arteriosclerosis in our clinic twenty-four cases show a definite increase in pressure while five show no such increase. The condition of the radial artery as determined by palpation does not give a clue to the condition of the other vessels. Severe involvement of the renal and splanchnic arteries may be present with only slight thickening of the radial artery.

The great majority of hypertension cases show pathological changes in the kidney or its bloodvessels. Cases where during life no kidney dysfunction was demonstrable have been found on autopsy to show definite kidney lesions. Some cases of hypertension with no demonstrable kidney lesion on autopsy, have been reported, but these are rare.

ETIOLOGY OF HYPERTENSION

In 1836 Richard Bright first described the disease which now bears his name, and suggested as a cause of the cardiac hypertrophy so often found in these cases, even in the absence of valvular defect, 1, "That the altered quality of the blood affords irregular and unwonted stimulus to the organ immediately; or 2, that it so affected the minute and capillary circulation as to render greater action necessary to force the blood through the distant subdivisions of the vascular system." These two suggestions form the basis of the voluminous literature which has accumulated upon clinical and experimental data to account for nephritic as well as other forms of hypertension. At present the direct cause of hypertension is still unknown. We must also plead ignorance to the fact whether hypertension is always the expression of the same causative factor or whether different causes can bring about the same permanent rise in blood pressure. A uniform conception of the cause of this abnormality if plausible would bring us a step further in the management of the disease.

THE MECHANICAL THEORIES

Traube attributed nephritic hypertension to the resistance of the blood in the occluded kidney vessels.

Katzenstein has reported that in a dog partial occlusion of the renal arteries leads to an increased pressure. These results could not be corroborated by other workers, and it was pointed out from the clinical side that amyloid disease of the kidney where the glomeruli are extensively diseased, in its pure form is not associated with a high pressure. So that this theory of nephritic hypertension being due to a resistance in the kidney,is generally discarded.

TABLE I

HIGH SYSTOLIC COMBINED WITH LOW DIASTOLIC PRESSURE. READINGS TAKEN ON DIFFERENT DATES. NOTE THE MARKED FLUCTUATIONS IN BLOOD PRESSURE.

Case No.	Systolic/Diastolic								
3	180/100	150/75	170/85	180/90	200/90

CHEMICAL THEORIES

It is the trend of modern medical opinion to consider hypertension as a distinct entity which may occur alone or be associated with nephritis, but the cause of the hypertension is probably the same in the two conditions. According to Warfield "hypertension is a physiological response on the part of the organism in order to maintain the circulation in equilibrium in the face of conditions which tend to produce vasoconstriction in large areas and, therefore, tend to deprive these areas of blood." He also states "that there must be some substance in the blood stream which causes the constriction seems certain." These statements represent our modern belief as to the cause of hypertension and follow the suggestion of Bright, that an altered composition of the blood might account for the cardiovascular changes. What substance in the blood causes the vasoconstriction is of course unknown. It is certainly not the retention of the ordinary metabolites. Repeated blood chemistry done on our hypertension cases in the clinic fail to show any definite relation between the amount of nonnitrogenous retention products in the blood and the degree of hypertension.

Many attempts have been made to identify this pressor substance. A substance renin has been extracted from the rabbit's kidney by Tigerstedt and Bergman which when injected into animals increased arterial tension. It has been claimed that autolysis of the pathological kidney causes this substance to enter the circulation and exert its pressor effect. Gubar found that the blood serum of nephritics has vasoconstricting properties. Voegtlin and Macht have isolated a crystalline substance from the blood and adrenal cortex which is related to cholesterin and acts as a vasoconstrictor. Ascoli found that nephritic serum has hypertensive properties while others have found vasoconstrictor substances in increased quantities in the diseased kidney. While these assertions were widely quoted Pearce showed definitely in 1908 that nephrotoxins are not specific. It has also been pointed out by Janeway that "hypertension is most extreme in those intensely chronic types of nephritis in which breaking down of kidney substance must be at a minimum if there is any at all."

TABLE II

SYSTOLIC AND DIASTOLIC PRESSURES IN NEPHRITIS

Case No.	Pressure Readings	Urine			Blood Chemistry (Mlg. per 100 c.c blood)						Grounds	Associated signs
		Albumin	Casts	Sugar	Urea Conc.	N.P.N.	Urea	Creat	Uric Acid	Sugar	Eye

EPINEPHRIN

Neusser first suggested the hypothesis that nephritic hypertension is due to an increase in the activity of the suprarenals. In support of this theory it was pointed to the hyperglycemia associated with hypertension. In this series of about fifty cases there are twenty with little or no hyperglycemia. Those showing a definite rise in blood sugar we feel justified in assuming as a result of careful observation, that an actual carbohydrate storage deficiency exists due most likely to sclerotic changes in the islands of Langerhans. Dietetic and insulin treatment brings the blood sugar down to normal but does not affect the blood pressure. It may be of some interest to note that some hypertension cases respond to hypodermic injection of adrenalin with a lowering of systolic pressure. We have injected 5 min. of adrenalin subcutaneously, and found a definite drop in the pressure in some cases in spite of marked systemic action of the adrenalin as evidenced by tremor, pallor, forcible action of the heart and increased pulse rate.

Cholesterinemia by some and an excess of dimethylguanidin sulphate in the blood by others have been considered the cause of hypertension. At the present these are theories which one may accept or reject.

Assuming the cause of hypertension to be due to some pressor substance retained in the blood causing vasoconstriction, it is rather hard to account for the marked fluctuations in pressure found in many of these cases. It is difficult to conceive of this substance being disposed of by the organism only to appear again at such irregular intervals. From the cardiodynamics point of view an increased peripheral resistance causes an increase of diastolic as well as of systolic pressures. Wiggers states that "if peripheral resistance is increased both systolic and diastolic pressures progressively increase, the diastolic pressure rising more than the systolic. Almost fifty per cent. of this series of cases show little increase in diastolic pressure, regardless of the height of the systolic pressure. Only our frank nephritis cases show a decided tendency to high diastolic pressures and this tendency seems to bear a definite relation to the amount of the nitrogen retention products in the blood. These outstanding clinical facts would argue, it seems to me, against vasoconstriction and increased peripheral resistance being the only feature in the pathogenesis of hypertension.

HEREDITY

Clinically one gets the impression that there is a definite hereditary tendency to hypertension. I have been able to obtain a definite history of hypertension in the immediate family in fifteen out of seventy-five consecutive cases. I have also found that the blood pressure in the young offspring of hypertension cases is not infrequently definitely above what would be considered normal for the age. In one family where both parents were affected I have found the oldest son to have a systolic pressure of 220 and a diastolic pressure of 120. One son had a pressure of 190 while one girl twenty-one years of age had a pressure of 150 mm. mercury. Three other children in the family I was not able to examine.

A hypertension case is as a rule an individual peculiar to his class. A patient who on examination discloses no abnormality outside the increased blood pressure, when questioned will state that they experience a peculiar sensation in the epigastrium on the slightest emotional disturbance. The meeting of an undesirable person, even the anticipation of meeting one, is associated with a sinking sensation in the epigastrium, forcible beating of the heart, pulsating bloodvessels, flushing of the face and mental confusion. The mere thought of some new experience brings about an undue cardiac response. In other words, these people instead of responding to mental stimuli with accelerated cerebration, increased attention and augmented mental capacity with but slight increase in the heart action, respond with a cardiac explosion, an abnormal rise in blood pressure and mental confusion. The abnormal responses repeated many times a day may account for the marked variation in blood pressure these people show not only from day to day, but also within short periods of the same day. Eskil Kylin considers essential hypertension as a functional disturbance associated with various nervous manifestations. Kylin and Fahrenkemp have pointed out a group of blood pressure cases which are distinguished by its extreme variability. Leo Hahn has classified a group of cases under the name of Chronic Intermittent Hypertension, the most characterisic sign being not so much the height as the variability of the blood pressure curve. In our series of cases there are twenty with marked fluctuation in systolic pressure.

SIGNS AND SYMPTOMS

Patients with hypertension may not register any complaint for a number of years, but sooner or later a certain train of symptoms appear related to the cardiovascular, renal, gastrointestinal, nervous, ocular, and aural systems. As to which type of symptoms will predominate in an individual case, depends primarily on the extent of vascular involvement of a particular organ or group of organs.

Nervous Symptoms.—Headache, often occipital pressure, a sensation of fullness in the head, nervousness, irritability, inability to concentrate, insomnia, migraine, tingling, numbness, transitory aphasia, sweating of the hands and feet and flushing of the face.

Cardiovascular symptoms.—Even early in the disease when the heart hypertrophies to meet the demand for increased work, and before any dilatation sets in, the patient is apt to become conscious of his limitations for sudden physical effort. The patient apparently in the prime of life and in good physical condition, will begin to complain of becoming winded on exertion. Climbing of stairs and running would be accompanied by slight precordial pain. Later on as dilatation occurs, the patient begins to complain of tachycardia, dyspnea, and palpitation even on slight exertion. Severe angina, muscular cramps, sudden attacks of night asthma, and pulmonary edema are late and dangerous symptoms. Recurrent epistaxis which may become severe is sometimes found in these cases.

Gastrointestinal symptoms.—Hyperacidity, distention, belching, epigastric pain which may be very severe and lasting, flatulence and constipation.

Renal symptoms.—Polyuria with nocturnal micturition is rather an early and universal symptom. In the urine which is of low specific gravity one usually finds a trace of albumin and on careful search almost always some casts. The kidney functional tests are negative at the beginning and only with a progressive disease of the kidneys can diminished function by these tests be shown. Increased retention in the blood urea is not found in uncomplicated cases. Increase of sodium chloride in the blood is not characteristic of hypertension. Hyperglycemia is found in some cases, but as the blood sugar can be lowered by dieting without at the same time reducing the blood pressure, the relationship between the two is not clear.

The ocular symptoms may be transitory, due to no definite organic changes, or permanent, and the result of sclerosis of the retinal vessels, hemorrhages, and atrophy. Tinnitus aurium and vertigo are frequent symptoms of hypertension.

On inspection two types of patients are to be distinguished according to Volhard, the red hypertension type where the patient has a plethoric robust appearance and the pale hypertension type. The red type he attributes to the fact that the skin capillaries do not participate in the spasm of the internal arterioles while in the pale type the whole system of capillaries both superficial and deep are contracted.

Hypertrophy of the heart comes early and may reach extreme dimensions. Such hearts are among the largest met with in the pathology of this organ. Later on we get cardiac dilatation which may lead to death.

The treatment of hypertension is as uncertain as its etiology. We have tried in our clinic everything from the old fashioned nitrites and iodides down to protein therapy. The marked spontaneous variations in pressure usually mislead one as to the efficacy of a certain remedy. Early cases present the best hope for controlling the condition. Blood pressures of 150 to 160 we were able to bring down for periods of months by undernutrition, rest and sedatives, but as soon as the patients resume their previous routine of life the pressure tends to rise again. Blood pressures of 200 or more can only be brought down by absolute rest in bed. Of all the sedatives luminal is perhaps the best to allay the irritability and bring down the pressure, but it fails as often as it succeeds.

Arterial hypotension.—Hypotension, by which we mean a systolic pressure below 115 mm., is usually associated with a diastolic pressure below 80. This condition is found after hemorrhage, in acute infectious diseases, convalescence from prolonged disease, in malnutrition cases, and cachexias such as accompany tuberculosis, malignancy and Addison's disease. There is a class of hypotension cases where the anomaly is a constitutional expression of inferiority. This class is designated as constitutional low arterial pressure or essential hypotension. These people are apparently not sick but they are not robust, they tire easily and are incapable of prolonged physical or mental effort. They complain of cold and moist extremities, suffer from dyspepsia, headache, lassitude, mental depression and constipation. They are often high strung individuals, easily upset and moody. Some are very sensitive to nicotine and caffeine as well as to atmospheric and barometric fluctuations.

The cause of hypotension in these cases is ascribed to lack of tonus of the arterial wall causing vascular stasis mainly in the splanchnic area. As a result too little blood reaches the heart, the heart output is small and the blood tension low. The coordinating mechanism of the vasomotor system, so important in man who has assumed the upright position, is apparently not functioning in these people. Cholin and histamine—the latter may be formed in the intestinal tract by the action of the bacillus aminophylus intestinalis upon amino acids—have been claimed as the cause of chronic hypotension.

On physical examination one very often finds in these cases a splanchnoptosis with ptosed stomach, hepatic and splenic flexures. The duodenum may reach down to the lower border of the fourth lumbar vertebra. The muscles are soft and flabby and incapable of sustained contraction. The kidneys are often ptosed, and by kinking of the ureters or the renal vessels may give rise to a complex picture of urinary disturbances.

244 East Fifteenth Street.

On the Etiology of Cancer

LEVERETT D. BRISTOL, M.D., Dr.P.H.
New York

It is becoming increasingly evident that neither the microscope nor the ultramicroscope will ever reveal a specific microorganism as the cause of cancer. It would seem, therefore, that we must look more searchingly into the fields of physiology, biophysics and biochemistry for the elucidation of the etiology of this disease, which at present is third in rank as a cause of death in many of our communities, outnumbered only by heart disease and pneumonia.

In 1919, the writer (1) called attention to the possible relation of localized accumulations of uncontrolled lymphocytic enzymes to cancer, based on previous studies and publications (2) on the subject. Since that time, more evidence has been forthcoming to strengthen this hypothesis.

Possibly the one outstanding fact demonstrated as a result of careful clinical and pathological research, with regard to the etiology of malignant disease, is its rather definite relation to chronic cell and tissue injury and the resulting reaction of chronic inflammation.

One of the cardinal microscopic signs of chronic inflammation is the socalled small round cell infiltration or localized accumulation of lymphocytes. In the past, a large percentage of investigators have recognized the relation of chronic tissue injury and inflammation to cancerous development, but sufficient attention has not been given to the possible importance of the lymphocyte, with its comparatively large enzyme, bearing nucleus, as an intermediary between

chronic inflammatory reaction, normal repair and malignant development.

On the assumption that one of the chief functions of the lymphocyte is to carry growth promoting and repair stimulating enzymes to body cells and tissues in general, it seems reasonable to suggest that due to chronic injury and inflammation from all sources (physical, chemical or parasitic) the chronic accumulation and localization of these powerful little storehouses (lymphocytes) of nuclear enzymes and growth promoting energy, at any one point in the body, may give rise even to a permanent abnormal growth and reproduction of neighboring cells and tissues; resulting in malignancy in those individuals in whom the normal defensive mechanism to cell or tissue overgrowth is temporarily or permanently absent or destroyed.

The investigations of Carrel on socalled leucocytic trephones (3) demonstrates that the lymphocytes truly may be considered as storehouses of growth enzymes and energy. After cultivating fibroblasts in serum for eight days, during which time they were subject to degenerative changes, Carrel was able to show a spontaneous rejuvenation of such fibroblasts by the stimulating influence of nearby lymphocytes. He noted, also, that the rate of proliferation of fibroblasts was increased severalfold when they grew near colonies of lymphocytes. From this it is concluded that lymphocytes are endowed with a function of primary importance in the nutrition and growth of tissues.

If lymphocytes, as noted above, are so definitely related to the physiological nutrition and growth of body tissues, it seems logical to point out that these same stimulating and energy bearing cells of the circulation, under variable conditions of localization, concentration and lack of control may give rise at times to abnormal nutrition, atypical and aberrant growth, and lawless reproduction of neighboring cells and tissues.

Mental and Physical Rest in Pulmonary Tuberculosis*

S. ADOLPHUS KNOPF, M.D.
New York

(*Concluded from page* 669)

We may now proceed to discuss briefly the means to obtain additional local rest for the invaded lung. Our thoughts of course go first to artificial pneumothorax. On its indications and contraindications volumes have already been written and it is not necessary for me to repeat even the essentials of this valuable means to obtain local rest by partial or complete collapse. The principal limitation to this procedure rests in the difficulty of applying it because of the frequency of pleuritic adhesions. Jacobaeus's operation (8), which consists in dividing pleuritic adhesions with the aid of the thoracoscope and the lung cautery protected by a cannula, is to the best of my knowledge rarely resorted to because of the danger of coming across vascular adhesions and causing subsequent serious hemorrhages. In view of the frequent unpleasant and even dangerous sequelæ, artificial pneumothorax is a remedy which should be applied only when conditions warrant its long continued use under most careful medical supervision and, in the earlier cases, only where other means for rest have failed and the disease has a tendency toward progression.

I do not stand alone in holding this view. It is coming to be more and more accepted by careful phthisiotherapeutists. Over three years ago Pottenger (9) made the following statement: "Pneumothorax should not be considered a cure for tuberculosis. I do not find it indicated except in a very small group of cases. Any patient who can get a result without pneumothorax is better off than one who has had his lungs compressed." Swezey of Denver (10) in reporting recently more than two hundred cases, says that advanced lesions in the good lung contraindicate the treatment. "As to all other cases, while the balance of evidence seems to be slightly in favor of the treatment, yet, considering especially the frequency of complications resulting from this treatment in such cases, it is probably best not to be too optimistic about it." Lawrason Brown (11), who is an enthusiastic advocate of prolonged bed rest, tries posture treatment for two or three months, as recommended by Webb (12), and only if this fails does he recommend a trial of artificial pneumothorax.

There are, of course, safe methods for immobilization of the lung by external means. We have Edison's adhesive straps (Fig. 2), used with the aid of Lilienthal's elastikon (Fig. 3). This method is particularly indicated when the chest must be entirely encircled. The elastic band allows the less affected side to expand and breathe comfortably, while the opposite side with the aid of ordinary adhesive straps over the nonirritating elastikon is made virtually immobile. Moreover, there are Forster's plaster of Paris jacket (Fig. 4), which permits the compression of the apex of the upper lobe in part or entirely with the aid of inflatable rubber bulbs; Sewall's belt (Fig. 5); David A. Stewart's Manitoba appliance for partial immobilization (Fig. 6); the St. Louis pneumatic pulmostat (Fig. 7); S. H. Stewart's English lung splint (Fig. 8); and my own saddle bag (Fig. 9). The illustrations of the five latter appliances explain themselves.

Besides these appliances for restricting respiration we must not fail to mention Webb's posture treat-

*Read by invitation before the Philadelphia County Medical Society, May 12, 1926, and in French before the IXe *Congrès de l'Association des Médecins de Langue Française de l'Amérique du Nord,* Montreal, September 22, 1926.

ment as an important and practical means to procure rest for the afflicted lung during sleep, or even during the day when the patient is resting in bed or on the reclining chair. Besides urging the patient to sleep on the affected side Webb places under the dependent side a small firm pillow to restrain motion of lung to a greater degree (24). Sometimes a belt or bandage pinned or buckled so that it can be easily removed if the patients, especially those in the advanced stages of the disease, experience a feeling of suffocation, may be put around the other portion of the thorax to help in teaching how to limit the respiratory movement. Lawrason Brown (25), who is an enthusiastic advocate of prolonged bed rest, tries posture treatment for two or three months as recommended by Webb, and only if this fails, does he recommend the trial of artificial pneumothorax.

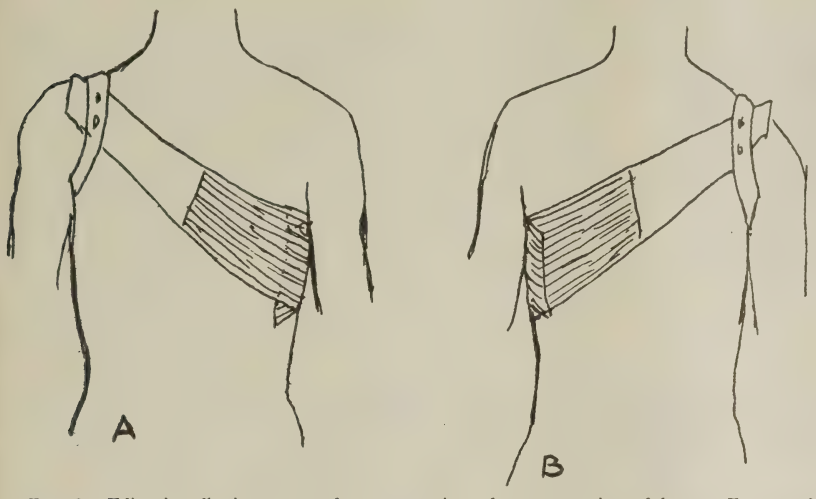

FIG. 2.—Edison's adhesive straps, for compression of upper portion of lungs. Front and back views.

In addition to any of the appliances here illustrated and described or without them, and in fact long before their use might become indicated, there is a method of reducing the activity of the invaded lung and limiting the respiratory movements to the lower lobes.

As is well known, in the vast majority of cases the tuberculous lesion begins in the apices or the upper lobes. It is obvious that in such cases diaphragmatic respiration is particularly indicated.

The story of how I came to work out this method is simple. Realizing the many failures in the administration of artificial pneumothorax and that the external restricting measures are not always easy to apply and can never be complete, I sought for additional means to help in giving the lung the much needed local rest. Observing animal life and from the study of comparative physiology, I noticed that the slow breathing animal seems to be the longest lived and least susceptible to tuberculosis. The rabbit which is one of the most susceptible animals to tuberculosis, particularly to the bovine type, breathes fifty-five times per minute; the adult guineapig eighty times; the young guineapig 140 times a minute. It is well known that the latter is very susceptible to both types of tuberculosis. The horse which of all the domestic animals is the least susceptible to tuberculosis, breathes only ten times a minute when at rest, but the cow and the calf, breathing eighteen to twenty-five times, contract tuberculosis most readily. The animal which perhaps lives longest is the turtle, and its respirations are so few per minute that they are hardly perceptible. Its resistance to human tuberculosis inspired Friedmann to make his vaccine which alas, up to now, has not proven what the inventor claimed for it.

Now, if the slowly breathing animal is least susceptible to the invasion of tuberculosis, and the lung invaded by tuberculosis is benefited by restriction of its respiratory movement through outside pressure, or by the complete arrest of function by means of an air splint (artificial pneumothorax) or bone compression (thoracoplasty), why should not restricted respiratory movements and reduction in their number by voluntary effort be equally valuable as an adjuvant in the cure of pulmonary tuberculosis? I experimented on myself and have been able to reduce my respirations, without discomfort, to eight, six, and sometimes five per minute.

However, prior to trying the method on my patients, I consulted Dr. Graham Lusk, professor of physiology at Cornell University, about the possibility of doing harm by an accumulation of carbon dioxide.

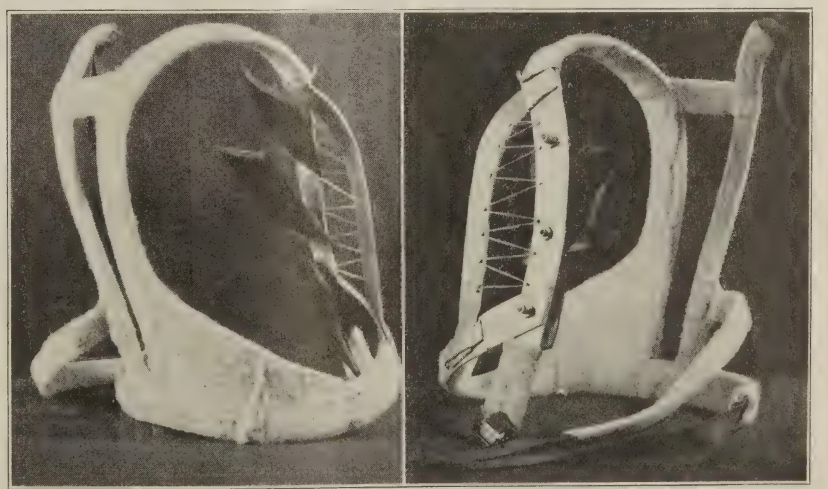

FIG. 4.—Forster's plaster of Paris jacket, permitting the compression of the apex of the upper lobes in part or entirely, with the aid of inflatable rubber bulbs.

I demonstrated for him this method of breathing, and to his surprise I was able to reduce my respirations to four per minute. He told me that in his opinion no possible harm could be done to any one by using superficial respiration or restricting the number of respirations per minute. Wishing to have

something authentic on the subject I asked him to be good enough to write me his opinion with permission to use it in an article which I was intending to prepare on the physiological restriction of respiratory movements, and he most kindly wrote me as follows:

"Under ordinary conditions the production of carbon dioxide in the tissues controls the volume of the respiration. If the number of respirations per minute

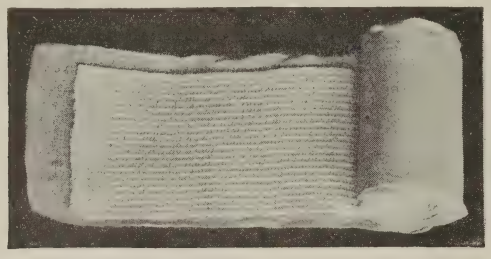

Fig. 3.—Lilienthal's Elastikon (adhesive plaster) which may be used for the Edison method of strapping. On account of its elasticity it is especially useful when the chest must be encircled entirely.

be decreased, the volume of air expired and inspired per breath is automatically increased. The total gaseous exchange, however, remains approximately the same. Under ordinary conditions of rest the quantity of oxygen absorbed is almost the same whether there be seven or fifteen respirations per minute."

Through the courtesy of Professor Lusk and with the valuable cooperation of Dr. D. P. Barr of the Russell Sage Institute of Pathology, I was permitted to make some spirometric tests during the respirations restricted in number and limited to the diaphragmatic mode of breathing. Dr. Barr, now professor of medicine at St. Louis, kindly lent himself to the experiment. After I had demonstrated to him how he could diminish the number of respirations to five per minute and limit them to the basal portion of the lungs, he was surprised to find with what comfort he could do it, and thought he could do it indefinitely.

On a recent visit to the Mayo Clinic, I had the honor of demonstrating the method of controlled diaphragmatic respiration before the large number of visiting physicians studying internal medicine under the leadership of Dr. Lemon. Thanks to the courtesy of the Mayo brothers and Dr. Walter M. Boothby, their chief of the metabolic service, it was also my privilege to have some metabolic tests made in connection with the method of rest breathing. These tests proved that there was a difference of less than one half per cent. between the intake of oxygen and giving out of carbon dioxide under the two conditions; that is to say, during normal and during controlled diaphragmatic breathing. The change in the basal metabolic rate was from -3 to -1, which, as Dr. Boothby says, is without significance. The respiration was reduced by half during the controlled diaphragmatic breathing and the pulse rate three per minute. Aside from these laboratory demonstrations we know from clinical observation that the patient can live and breathe comfortably even if the left or the right side of the lung is partially or totally compressed by artificial pneumothorax or external thoracoplasty.

The patient should be made to understand the necessity of shallow breathing when he is not using the diaphragmatic method, and of course should, as already stated, never cough unless he feels the necessity of expectorating. It goes without saying that just as the general rest cure must always be carried out where the air is fresh and pure, so should it be with the rest breathing. In cold weather the feet should be warmed with the aid of hot water bottles or bags, and in summer a comfortably cool place should be chosen.

The tuberculous invalid should be convinced of the fact that if he has the good will, patience, and perseverance to carry out the rest breathing method conscientiously and in a cheerful and hopeful frame of mind, he will surely derive great benefit from it, and it will lead him to a more rapid recovery. Whenever sad or depressing thoughts come over him, he will easily dispel them by concentrating his mind on diaphragmatic and restricted breathing, something which he himself can do toward bringing about his own recovery. Now as to the *modus operandi.*

The best position for the patient to assume when being taught the practice of controlled diaphragmatic breathing is to lie in or on the bed in a semireclining position, with feet extended and slightly separated, which position demands the least cardiac efforts against gravity. This position can be best obtained in bed by the use of two or three pillows, and later on may be imitated as closely as possible on the typical sanatorium reclining chair, such as is illustrated on page 667 by regulating the back of the chair so as to be at an angle of 30°. In this position relaxation is most easily obtained and the heart is called upon to do the least work. It goes without saying that if the patient is dressed there must not be any garment that would restrict the free exercises of the diaphragm and abdominal muscles.

Before beginning the rest breathing it is presumed that as the result of the explanation and instructions given him beforehand, the patient will be relaxed in mind and body. This relaxation of the body is essential and whatever muscular effort is exerted during

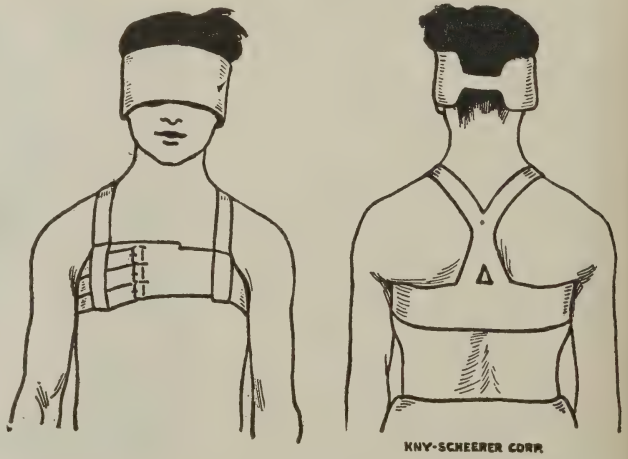

Fig. 5.—Sewall's belt for compression of the chest; anterior and posterior views.

the breathing exercises should be as slight as possible. He is then told to imagine that the respiratory movement begins in the toes of the right foot, the inhalation gradually traveling upward as far as the diaphragm on the right side, then crossing over to the left, and gradually descending during exhalation downward to the left foot. While, of course, this

breathing upward from the toes to the abdomen is merely imaginary, it results in a diaphragmatic breathing and whatever quantity of air is inhaled passes mainly through the lower portions of the lungs while the upper portions, where tuberculous lesions are usually located, are put, if not entirely, at least at comparative rest.

Before leaving the patient, the physician should count the number of respirations per minute with watch in hand, and thus see what can be accomplished. This is particularly indicated with highly nervous and dyspneic patients, who must be shown what patience and perseverance can achieve in the reduction of respiratory movements. This class of patients often take many short, jerky breaths per minute and seem to have no control over their diaphragm. They must be assured that they will learn with practice and may begin by stopping a few seconds after exhaling, which is the easiest part of the procedure They will learn to stop also after inhalation and learn the use of the diaphragm. It is surprising how easily the average patient learns to reduce the number of respirations per minute by not breathing at all for a few seconds after exhalation.

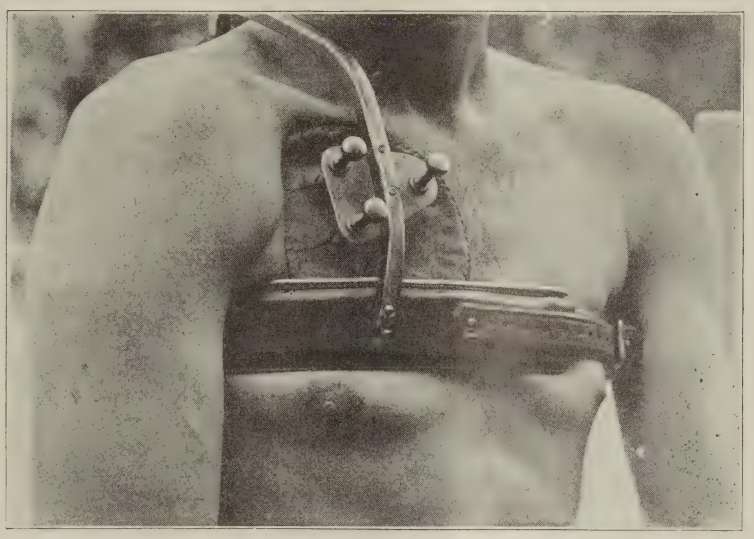

Fig. 6.—David A. Stewart's Manitoba Apparatus for compression of the chest, which must be fitted to effect compression where most desired.

Although we believe that by our spirometric and metabolic tests and clinical observations we have demonstrated that in controlled diaphragmatic respiration there results no air hunger and no increase of carbon dioxide, some patients might feel the desire for deep inhalation or for more rapid breathing after the prescribed exercise. The possibility of harm being done by a true or imaginary effort to compensate the air supply can be overcome by teaching the patient to return only gradually to his normal type of breathing. Dr. Martin F. Sloan, the director of the Maple Heights Sanatorium, at Sparks, Md., who has tried the controlled diaphragmatic respiration extensively, uses this precaution of gradual return to the previous mode of respiration. He is convinced that this prevents an acceleration of the respiratory movements likely to counterbalance the effect of the limited movements.

For how long a time and how often should the patient resort to this slow and controlled diaphragmatic breathing?

If the patient is a bed case, he may be told that since it cannot do him any harm and that with every additional minute of rest he gives his lungs, his condition is bound to improve, he should do it whenever he feels like it, and as long a time as he enjoys it. At the beginning the patient may not be able to take this rest breathing for more than a few minutes at a time. Some are able to do it right from the start for five minutes at a time, others even for ten. Fifteen minutes is in most instances the maximum duration for continued rest breathing. The patient may resume another period of rest breathing as soon as he feels like it, but he should bear in mind that whenever he is not practising the controlled diaphragmatic respiration, his breathing should be quiet and rather shallow. He will not suffer from air hunger by so doing.

The fakirs of India who have been mystifying European audiences by allowing themselves to be buried for considerable lengths of time, are able to do this trick by economizing the little oxygen at their disposal by remarkably shallow breathing. They are thus reducing the interchange of oxygen and carbon dioxide to the lowest possible minimum. Our own Houdini, who passed away recently, practised the same method and far outdid the Indian fakirs by remaining buried twice as long as the one who challenged him to imitate the burial trick.

Ambulant cases, who are up and about but still taking the cure, should do the rest breathing whenever they can, particularly in the morning after awakening, during the day when having their rest hours, and in the evening before going to sleep. Ambulatory and afebrile cases, who, for one reason or another are obliged to work, might take the rest breathing when in a sitting position and be able to do it without interfering with their work. Of course, above all it should be done in the morning before rising, and in the evening after having retired. This breathing may also be practised at night if a patient is wakeful. In many cases, if done quietly and regularly, it will be found conducive to sleep.

Experience has shown that diaphragmatic breathing, after being practised for a length of time, will become automatic and thus be of continued benefit to the patient until the complete arrest of the disease is accomplished, and even protect him from the danger of a relapse.

To make rest breathing more interesting to the indifferent patient, he may be told to write down the number of diaphragmatic respirations he has taken per minute and the number of minutes he has persisted in the procedure, and then calculate at the end of the day how many respirations he has saved his lungs by having breathed only four, five, six, or ten times a minute instead of twenty or more times, whatever the number of respiration prior to begin-

ning the treatment. Of course he cannot do this without having a time piece. If there is no clock where he can easily see the dial, a small clock or watch should be placed on a stand near the bed or suspended nearby so that the patient will not have to tire his arm or hand taking out a watch every few minutes. If he succeeds in reducing his respirations from twenty even only to ten per minute and the

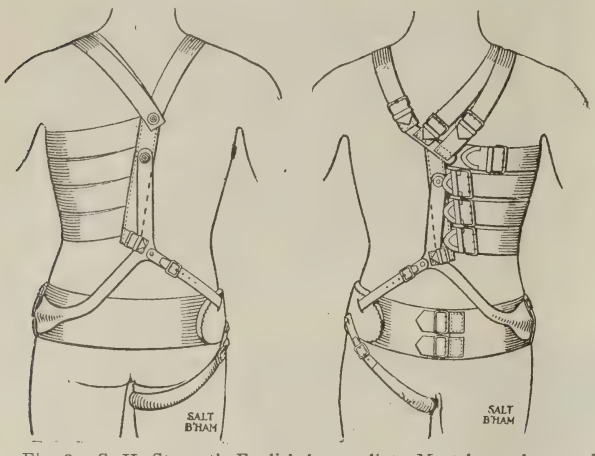

Fig. 8.—S. H. Stewart's English lung splint. Must be made according to measurement. Obtainable from Dr. Stewart, Edinburgh, or through American dealers in instruments.

periods of several minutes of rest breathing arrive at a total of five hours, he will have saved his lungs three thousand respirations or six thousand movements. Let him also bear in mind that by this physical and mental rest his pulse will become slower and his heart more quiet, and that this rest breathing cannot possibly harm but can only benefit his general condition.

When one considers that by this method of breathing not only the lungs but the heart also is spared many a movement and energy is thus preserved to a considerable extent, its value must be obvious. According to the latest edition of Howell's textbook (13), the total work done by the left ventricle at each systole is equal to 20,085 grams centimetre. By reducing this to pounds and feet, it figured about one and a half foot pound for each contraction of the left ventricle. Lawrason Brown (14) estimates that the right ventricle does one half pound of work. This added would make the work performed by the heart about two pounds for each systole. Thus if with each normal heart beat an energy equal to two pounds is exerted, and by reduced and restricted breathing we save the heart two or three contractions per minute, we spare the heart from 1200 to 1800 foot pounds of energy in five hours.

Diaphragmatic breathing will also cause a better circulation in the lower extremities and abdominal viscera, especially aiding the hepatic function, all of which is so essential for patients who are ordered complete physical rest on a reclining chair or in bed.

I have been asked whether women who, for biological reasons, do not use the diaphragm in breathing as much as men do, can adopt this physiological adjuvant. Whether or not it is because of the abandonment of tightly laced corsets that I have had no difficulty in this respect, I do not know. At any rate, I have also the assurance of Professor Joel E. Goldthwaite, of Boston, who has had such a large experience with cases in which he prescribes diaphragmatic breathing in order to correct faulty conditions due to postural or typical orthopedic deformities in women, that he has no difficulty whatsoever in making his female patients use diaphragmatic breathing.

When one starts out to recommend any new therapeutic measure for pulmonary tuberculosis, he should be most careful not to venture into this dangerous field without having counselled as many of the best minds as possible, and only after having their approval should he venture to give his suggestions to the medical public. I began my work on controlled diaphragmatic respiration while still in the United States Public Health Service at Hospital No. 61, later the Veterans Bureau Hospital at Fox Hills, New York. We had a great many tuberculous exsoldiers to take care of there. I made a report on my first experiences with controlled diaphragmatic respiration to the Surgeon General of the Service, and after confirmation by the Research Bureau I received the authorization for its publication. In the meantime I had written to a great many of our leading physiologists, clinicians and therapeutists to get their opinion and reports on the subject.

It would take far too much space to reproduce here all the opinions on the physiological soundness of this adjuvant or give the many clinical reports which have since come to me. I can quote only a few of them:

Sir Clifford Allbut, Regius Professor of Oxford, England: "The description of your method is lucid and reasonable and I have referred your system to the staff of our tuberculosis colony at Papworth."

Dr. Samuel W. Lambert, Professor of Medicine and Dean Emeritus of Columbia University Medical School: "I think you are presenting a new therapeutic measure and it will be a pleasure to cooperate in every possible way."

Dr. Louis W. Warfield, Professor of Internal Medicine, University of Michigan, writes: "It sounds very logical and it would seem to have a very definite place in the treatment of tuberculosis of the lungs."

Fig. 7.—St. Louis Pneumatic Pulmostate. A chest splint made according to measurements by the Therapeutic Appliance Corporation, St. Louis, Mo.

The clinical results have thus far been as encouraging as the physiological deductions. From the letter received from the Barlow Sanatorium, where Dr. George Dock, with the assistance of Dr. Munford Smith and Dr. O. F. Henning, carried on lengthy and extensive experiments, I quote the concluding remarks, which are as follows:

"Your method is a useful addition to the class treatment of tuberculous patients. The demonstrations and questions raised give many opportunities for learning the many problems and inhibitions of the 'lunger.' Like all methods that lead to closer cooperation between patient and therapeutists that work has had a distinctly good physiological effect. In written reports I have had the patients give me, I find

such statements as the following: Helps to relax, quiets the heart, lessens fatigue, increases endurance. I have a very strong impression that the more intelligent the patient the more benefit is he likely to receive from carrying out your adjuvant along with the other necessary measures."

Dr. M. Jacob, of the Eagleville Sanatorium, Pa.: "I feel happy to be able to report to you the number of cases which gave such astonishing results. Two cases in particular were of such character that I gave a very unfavorable prognosis when they first came under my care, but at present their recovery is practically assured, thanks to the restricted breathing which you have suggested not long ago."

FIG. 9.—Knopf's saddle bag for standing and recumbent position. Its pressure on the chest can be regulated in the standing position with the aid of straps or bands, in the recumbent position by the amount of lead shots or sand in the bag.

Dr. J. O. Marien, formerly in charge of the Gabriels Sanatorium, himself a tuberculous invalid, now of Saint Esprit, Quebec, writes: "I have tried your method with a number of patients at the sanatorium and can tell you that the results have been very encouraging. I have practised the diaphragmatic breathing myself since last July and the method has been most beneficial. My cough diminished considerably and is virtually gone now and so has the expectoration; the pain in the chest has entirely left me. Of course, I continue to practise the method which I consider one of the best adjuvants in the treatment of pulmonary tuberculosis."

The improvement or cure in any one particular case, as the result of any new treatment or therapeutic adjuvant in pulmonary tuberculosis, may have little value in itself and so only after giving the foregoing reports of a relatively large number of cases, would I wish to speak of the following one as a unique example to physicians and patients, of what will power and determination can accomplish when the suggested method is systematically carried out.

The following letter, which I received after the publication of my first extensive report on the results of diaphragmatic respiration, I have had no opportunity to publish before. Although I have now lost trace of the case, the report is as valuable, inspiring and helpful today as it was at the time it was written. The writer, an inmate of the United States War Veterans Hospital No. 60, at Oteen, N. C., sent this message unsolicited and without direction of his physician:

Oteen, N. C., February 28, 1925.

Dear Doctor Knopf:

About two years ago Dr. George S. Spence of this hospital, in a lecture to his ward patients spoke of your diaphragmatic breathing exercises. I took up the same (the last straw to me with far advanced pulmonary tuberculosis in all lobes with extensive cavitation in left lung and getting over a hemoptysis of date November 21, 1922). I put in a few minutes each day increasing the time per day as well as times for the day for taking this treatment. Having spent thirty-seven years as a compiler and statistical man for the Government, I put my efforts in "system" and have kept a complete record. For over a year I have put in four intervals of one hour each daily in slow diaphragmatic breathing. I can now get on with less than one respiration per minute per hour and do so with ease.

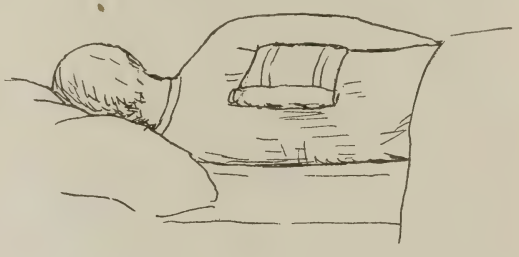
My x rays taken in six months intervals have been "conferenced" and show steady improvement. I have no doubt Dr. Spence would be glad to give you the clinical data and I will be glad to send you my original records and continue to send same each month. I have been on moderated exercise nearly twenty months and am feeling fine. Dr. Spence gives your treatment that credit for this wonderful change in my condition. He calls it "phenomenal." I think the accurate data will be of value to you and it's yours, Doctor, if you wish it.

With kindest regards to you and thanks that this treatment was available to me, I am, Sir,

Very truly yours,

B. C. Washington, Jr.

I allowed some time to elapse before writing to Dr. Spence for confirmation of the case. He graciously confirmed Mr. Washington's report in every respect. He doubtlessly will also do so to any one who may doubt the almost miraculous result of a simple treatment, available to all and as free as the air we breathe.



One word about the contraindications. A terminal case should be made comfortable by all possible means, and if controlled diaphragmatic breathing causes the tuberculous patient physical or only mental discomfort it should not be resorted to. There are also other contraindications, such as involvement of the lower lobes and pleuritic adhesions to the diaphragm so that diaphragmatic breathing is accompanied by pain. Pleuritic intestinal or peritoneal involvements which cause pain with diaphragmatic breathing are, of course, contraindications. Strange as it may seem, emphysema is sometimes relieved and sometimes aggravated by diaphragmatic breathing; the surest way is not to use it when it causes pain, increases cough, or discomfort.

In a complete or partial artificial pneumothorax controlled diaphragmatic respiration is not contraindicated unless it causes pain, discomfort, cough or distress. When at rest, in a recumbent position, the patient needs less oxygen for sustenance, and when the lower portions of both lungs are in fairly good condition dyspnea will rarely accompany or follow diaphragmatic breathing. In most cases the collapse is usually confined to the upper and middle portions of the lungs. During this rest breathing the lower portions of the lungs are doing the work and their better ventilation can only be considered beneficial.

Bearing in mind the contraindications just enumerated, the treatment can easily be employed in all stages of the disease, except in absolutely terminal cases. Even in ordinary third stage cases, when by patient teaching of the modus operandi the invalid can be made to realize the advantage of the procedure, it is bound to do him some good and relieve whatever distressing symptoms he may have. The only cases in which the treatment is really useless

are where the patients are too lazy or too indifferent, or for other reasons unwilling to carry out the instructions for reduced and diaphragmatic breathing.

The most satisfactory results from this physiological adjuvant to the rest cure of pulmonary tuberculosis can naturally be obtained in a sanatorium or hospital where the patients have come, so to speak, to occupy themselves with getting well, unless the patient has the "sanatorium treatment at home" under careful medical supervision.

Our great surgeons have of late provided us with another method of giving local rest to the invaded lung. The surgical manipulations to attain this end are manifold, such as phrenicotomy or avulsion of the phrenic nerve. This operation has for its purpose to paralyze the diaphragm and thus by its elevation reduce the lung volume. Another operation is Tuffier's extrapleural pneumolysis for apical tuberculosis, and last the all important extrapleural thoracoplasty. As to the indications, merits and technic of the various operations I must refer my readers to some of the many American and European authors who have so ably discussed the subject. For example, Alexander (15), Archibald (16), Brauer (17), Graham (18), Hedblom (19), Lilienthal (20), Willy Meyer (21), Sauerbruch (22), Saugman (23), Torek (24), Tuffier (25), etc. We phthisiotherapeutists are indeed greatly indebted to our surgical colleagues for having restored by extrapleural thoracoplasty and similar operations many a case which heretofore had to be considered as absolutely incurable. These operations, seemingly very serious and heroic, have restored not a few apparently hopeless cases to relative health and vigor.

Our thoracic surgeons are improving their technic and precautions constantly, thus lessening the seriousness of thoracoplasty and reducing the mortality of cases submitted to the operation to a minimum. As recently as November, 1926, Dr. C. H. Hedblom writes in the *Chicago Sanitarium Bulletin* as follows: "During the past eighteen months I have performed an extrapleural thoracoplasty on fifteen patients ill with pulmonary tuberculosis. All of these patients have improved, most of them to such an extent as to be practically symptomless, and all have gained in weight and strength."

May I say in conclusion that there is no question in my mind that the physician, particularly the skillful phthisiotherapeutist, who resorts to what we know today to be feasible to obtain general and local rest, will know when a case demands the aid of the thoracic surgeon, and thus will rarely fail to help his patients. To make himself thoroughly familiar with the psychical and mental state of the patient, will of course be equally essential and of an invaluable help. The success of the Christian Scientist in curing a so-called imaginary or functional disorder and at times making the patient feel better even when suffering from an actual organic disease, rests upon autosuggestion or suggestion by the socalled "practitioner," or both. The regularly educated physician with his training in pathology, diagnosis, and rational therapeutics, should and could do a great deal better than the Christian Science practitioner, usually totally ignorant of the science of medicine and surgery.

This autosuggestion or the physician's suggestion should not by any means consist of the absurd negation of the existence of disease, but by the patient's determination to get well, by the realization that the less his mind dwells on pain and discomfort the less he will feel and be aware of them. The physician, in his suggestion therapy, should work along the same line of thought and impress upon the patient the power of mind over body. The deeply religious patient must be told that prayer alone does not always help, but that there are many things God does not do until man cooperates with him. Persistence in optimism, cheerfulness, obedience to the physician's directions, and patience are some of the things which man can do for himself as coworker with God.

If the patient's condition is hopeless, assure him that by his concentration of mind on other matters not relating to his disease he will be more comfortable. Helpful medication is of course indicated in such a case. If there is a reasonable chance for improvement we should make the invalid feel that by directing his thoughts to improvement, he will improve. Favorable cases should be particularly impressed with the fact that their will to get well will help them materially toward recovery. I do not think that actually deceiving the patient about his condition is a wise policy; neither do I think it judicious to be so absolutely sure about complete recovery in even seemingly favorable cases. The greatest diagnosticians have, to my knowledge, erred in this way. With a little tact and skill one can always make hopeful suggestions without a definite prognosis.

Of course, the modern phthisiotherapeutist must be imbued with the great work which his high calling demands. He must be a doctor of the mind, body and soul, *"ein Arzt des Leibes und der Seele,"* as the Germans poetically call their great physicians. He must bring to his task a sympathetic heart and all possible gentleness and patience. At times, firmness may be essential, but this, too, can be expressed in such a way as not to make the patient feel unhappy. When the latter can be made to realize that his physician is his friend and really interested in his case, when the confidence in his medical adviser is unlimited, the battle is half won, and if it is humanly possible to restore the patient to health and vigor, he will be restored.

Chronic (Streptococcic) Hypertrophy of the Lower Lip

With Report of a Case

L. G. BEINHAUER, M.D.

Pittsburgh, Pa.

The reported cases of chronic hypertrophy of the lower lip due to the streptococcus are few.

Sequeira (1) reported a case of a girl aged seventeen, in which an acute swelling of the lower lip, resembling an attack of erysipelas, developed following an attack of facial palsy. The swelling subsided temporarily but after a series of attacks remained chronically enlarged complicating the facial palsy. Pernet (1) discussing Sequeira's case, recalled a similar case, seen with the late Radcliffe Crocker, of an old woman whose lower lip was involved. Wylie (2) reported a case of a young girl who developed a similar condition of the upper lip following vaccination. The patient also presented an interstitial keratitis, Hutchinsonian teeth and other stigmata of congenital syphilis. Gougerot (3) reported a case in a man, a cornet player by occupation, who developed a chronic enlargement of the lower lip presumably from an infection through an abrasion of the lip contracted while playing his instrument. White (4) reported a case in a young adult following a nasal eczema and was associated with edema of the face, carious teeth, and pediculosis capitis.

Questionable cases have been reported by Malherbe (5) and others (6).

Case.—J. N., aged nineteen, baker, presented a persistent swelling of the lower lip. The patient stated the condition developed from a fissured lip which he had three years previously. One week following the fissure, he noticed a marked swelling of the lip which lasted for one month, following which all swelling subsided. Since that time recurrences of the swelling have been frequent and at one period in the past two years the swelling subsided for one month, that being the longest period of freedom from attacks. For the past year the patient has had no relief from this condition and the chronic swelling has remained without any change at any time. Previous to being referred to me, the patient had two operative procedures, probably lymph drainage, each of which failed to produce any improvement. Following the operations, five filtered röntgen ray treatments were given with no beneficial results. The patient stated that an attack of cold in the head might precipitate an attack of swelling.

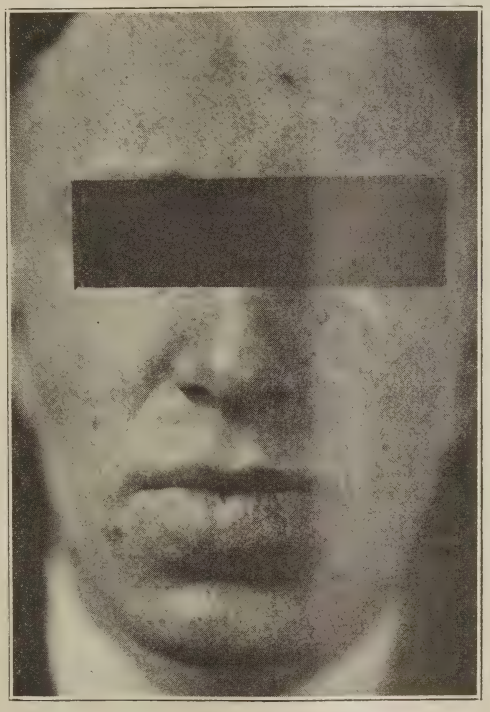

Fig. 1.—Note the rolled out mucocutaneous border, the healed median fissure, the thickness of the lip and scars from previous operations are present.

The lower lip showed a marked swelling involving the entire structure. The lip was bluish red, soft and very edematous at the first examination, although at subsequent examinations the consistency was more firm and interfered with his eating and speech. The mucous membrane was thickened and shiny and the mucocutaneous border varied from one half to one inch away from its normal site while the lip measured one or more inches in thickness at varying intervals. Scars were present on the skin and mucous surfaces, indicating the sites of previous operations. A healed scar located the original fissure. The teeth were fairly good with, however, moderate pyorrhea.

The tonsils were small, atrophic and with no evidence of inflammatory reaction. The mucous membranes were negative. The tongue was scrotal in type, apparently too large for the floor of the mouth. There was a slight accompanying glandular enlargement following the deep anterior cervical chain. The physical examination otherwise was negative. Röntgenograms of all teeth were negative. The blood Wassermann was negative. Cultures from the tonsillar crypts and teeth revealed a mixed Staphylococcus albus and a Streptococcus viridans. A lymph puncture was made from the deeper structures of the lip and a Streptococcus viridans was recovered.

An autogenous vaccine was made and the patient was given frequently repeated small doses with gratifying results. The lip was reduced half in size and the patient was comfortable having no disturbance while eating or talking. Ultraviolet ray exposures were given and the patient remained comfortable until the fall when following a head cold the swelling returned. At that time a thorough search was made of the nasopharynx and the tonsils were condemned and removal advised to which the patient would not consent. A lymph puncture was made and corroborated the previous findings. Ultraviolet therapy and an autogenous vaccine gave relief. The case was presented before the fourth annual meeting (1925) of the Pittsburgh Dermatological Society under the diagnosis of chronic streptococcus lymphangitis and therapeutic suggestions were asked. Radium was offered and accordingly, filtered radium applications were applied, giving no marked curative effects but instead the lip reduced somewhat in size and assumed a more solid consistency which becomes painful and

tender with recurrent attacks of swelling. Since first seen the patient had six attacks, each of which subsided under vaccine and ultraviolet light therapy.

ETIOLOGY

This condition is supposed to be more prevalent in people constantly irritating the mucous membranes of the lip; such as, musicians, glass blowers, and smokers. Constant biting of the lip is also a predisposing factor. It may follow erysipelas, eczema or other facial infections always gaining entrance through a fissured or abraded mucous membrane. Both sexes are equally attacked. The condition is chronic but is subject to acute exacerbations. Focal infection about the teeth, intranasal regions, tonsils and adenoids plays an important part in its production.

SYMPTOMS

The condition may give local or general symptoms depending upon the severity of the infecting organism. A feeling of tenseness and weight with occasional obstructive symptoms to eating and talking and pain are the common symptoms. The clinical picture is constant in all reported cases giving a tender, red, greatly swollen everted lip presenting a glazed, slightly thickened mucous surface with the portal of infection usually present. The glandular involvement is very slight.

This type of chronic hypertrophy must be differentiated from the group macrochilia due to neoplasm, tuberculosis, syphilis, filariasis, injury, hypertrophy of the mucous glands and other allied groups. Elephantiasis, chronic lymphostasis, macrochilia and chronic hypertrophy have been used interchangeably but chronic streptococcic hypertrophy of the lower lip is favored as the name of choice because it is the most descriptive.

TREATMENT

The treatment of this condition is very unsatisfactory. Radium and röntgen rays are of no benefit and are advised against because of the resultant fibrosis produced. Local injections of thiosinamine have no therapeutic value. Surgical procedures may be tried but give no permanent benefits. Of these the simple lymph drainage, the Handley and the complicated Kondoleon operations are the choice. Extirpation of the adjacent lymph glands offers another surgical procedure. The most effective treatment to combat the acute condition is repeated injections of small doses of autogenous vaccine. One must remember that any treatment used is only a palliative measure offering a partial reduction of the swelling and a temporary relief from its symptoms.

A Case of Penetrating Gastric Ulcer Healed Medically*

MONROE B. KUNSTLER, M.D.

New York

Our best judgment in the care of a patient is at times influenced by the circumstances of the case and the result may be a startling surprise to us as in the following case:

Case.—Mr. B., aged sixty-nine, salesman (referred by Dr. Lebenstein), first consulted me on November 19, 1924, with the following history: Two weeks previously, having been well up to then, he was seized with a sudden pressurelike pain in the epigastrium which radiated around the waist. There was no nausea, vomiting or black stool at any time and the appetite remained fairly good. The pain was constant with only slight relief from sodium bicarbonate and had no relation to food intake. There was moderate belching which relieved somewhat but no heartburn or regurgitation. Weight remained constant and he continued his work, which necessitated a great deal of walking. His habits were regular and the past as well as the family history were negative.

Physical examination showed a well preserved man with normal findings as to lungs, heart and abdomen except for a moderately enlarged and tender liver and tenderness in the epigastrium. No mass could be felt at any time but at certain periods rigidity could be determined in the left upper quadrant. The blood pressure was 130-80, weight 132 and Wassermann negative. The stool was negative for blood and the test meal showed free acid 20, total acid 30, blood negative, and much pus. At times there was a moderate retention of his breakfast for three to four hours as revealed by stomach washings. Under simple therapy he remained well until the

*Read before Mount Vernon Medical Society.

FIG. 1.—X ray photograph made in January, 1925, showing a large diverticulum in the posterior wall of the stomach.

beginning of January, 1925, when his appearance suddenly changed, there occurring a rapid loss of weight from 132 to 113 pounds with the development of a severe cough. The sputum was negative.

A röntgenological examination at this time (Fig. 1) showed a large diverticulum arising in the posterior wall of the stomach which was apparently due to a penetrating ulcer. When the stomach was completely full the sac could not be seen, but when about half the meal had been evacuated, it became clearly visible (Fig. 2). The question of malignancy arose owing to rapid loss of weight and a sudden onset of symptoms in a man of this age. But this point could not be definitely settled. Obviously surgery was indicated but owing to the patient's very poor condition and realizing the extent of the operation, medical

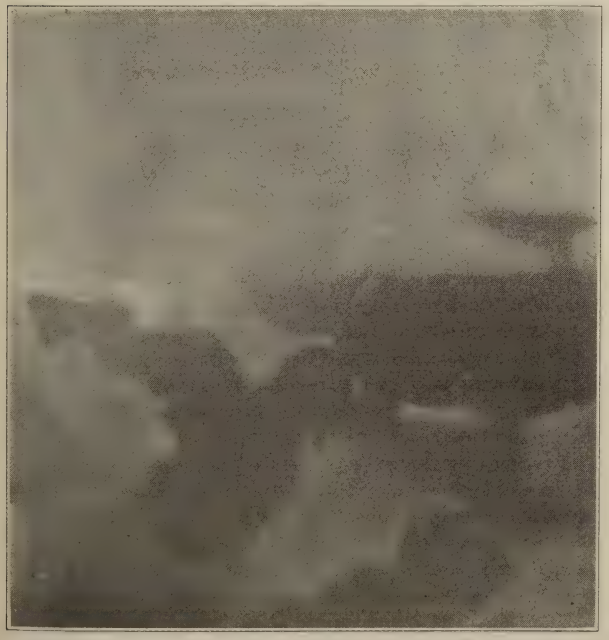

FIG. 2.—X ray photograph taken at the same time as Fig. 1. The diverticulum is clearly visible, about half the stomach contents having been evacuated.

treatment was decided on after due consultation with the family.

He was carried along on a strict modified Sippey diet for some weeks and the relief was almost instantaneous. The pouch gradually became smaller as revealed by fluoroscope and the weight increased rapidly so that by March 8th, he again weighed 132 pounds. The severe cough improved with the amelioration of his stomach symptoms. An x ray taken September 30, 1925 (Fig. 3) showed no diverticulum nor did careful fluoroscopy reveal any trace of the former condition, although a slight irregularity can still be seen on the lesser curvature. His weight is now 143 and though on a liberal diet, there is absolutely no return of any of the gastric symptoms. As a matter of fact he feels better than he has for many years.

While the time is too short to claim an absolute

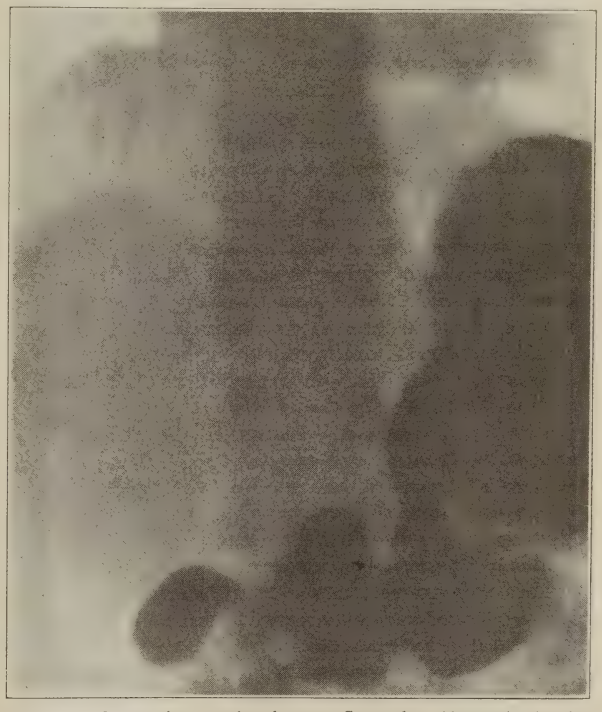

FIG. 3.—X ray photograph taken on September 30, 1925, showing no diverticulum. A slight irregularity on the lesser curvature can still be seen.

cure, still this is a symptomatic and röntgenological cure without any evidence at the present time of a recurrence. It demonstrates the marvelous healing power of the stomach and also of the fallacy of the theory that all penetrating ulcers on the lesser curvature need surgery. Unless there is extreme urgency, it is wise to give this type of case the benefit of medical treatment.

An interesting feature of the case was the development of the cough with the onset of severe gastric symptoms and its disappearance with the healing of the diverticulum. This was probably reflex in nature and due to irritation of the vagus ends in the stomach.

I wish to express my thanks to Dr. Lesser B. Groeschel for assistance in making the x ray examination.

At this time, October 1, 1926, the patient is still quite well.

Sex and Psychoanalysis

THEODORE SCHROEDER
Cos Cob, Conn.

First let me express some words of caution. Psychoanalytic theory is still in the making. Psychoanalysts manifest different degrees of freedom from unconsciously determined compulsions, as well as a great diversity in the quality and quantity of their experiential and cultural acquisition. Accordingly, there are great differences of emphasis, and some difference in the resultant psychological theory. To be fair, therefore, you should hold no one responsible for my views, but myself. I wish also to caution you that I do not expect to convince anyone, of the correctness of my views. The acceptance of these formulations is usually of little value, except when it is the product of a psychoanalytic discipline. Without that there will be too little of similarity in the related mental content. Therefore, I make no logical defense of my position and remain content with merely describing it.

I will weave my description of the psychoanalyst's attitude toward sex around a popular criticism aimed against psychoanalysis. I refer to the accusation that psychoanalysts overemphasize the importance of sex. Those who are the victims of even an unconscious subjective moralistic conflict, arising from their own psychosexual past, cannot be wholly comfortable, nor inwardly calm, in the presence of such dispassionate frankness, as that exhibited by psychoanalysts. This is so because by contrast and its negative suggestion, the psychoanalysts' discussion is sure to stimulate toward consciousness some thought or experience which would be painful to contemplate, in the presence of other persons, because of the existence of irreconcilable impulses in relation to it. Also, there is often an unconsciously determined anxiety, or a half conscious haunting suspicion that the psychoanalyst has an uncanny capacity for penetrating the secret recesses of human experiences, and discovering that which we are most anxious to conceal, or to deny. There is a third factor involved in this emotional aversion to psychoanalysis. Most of the victims of a subjective moralistic conflict rationalize one or another aspect of that conflict, so as to create an emotionally glorified and idealized self, quite out of harmony with the real personality, when considered as an organic unity. The cold hard scientific attitude and method of the psychoanalyst, is somehow instinctively and vaguely perceived as a constant menace to such secret delusions of grandeur, and to their fictive rationalizations.

Because the critics complain of our findings, apparently without understanding and certainly without criticizing our method of observation, we see the subjective moralistic conflict of impulse as being the more immediate emotional determinant for most of the adverse criticism that is being made of psychoanalytic hypotheses. This is so, because the psychoneurotic has an emotional need for publicly maintaining a high moral value for his delusional theory of the facts of life, which theories and valuations conflict with the realities as these are found by the use of the psychoanalytic method of observation. The problem is all the more difficult for our critics, because of the many unconscious factors involved in all such conflicts of irreconcilable impulses.

From the psychoanalytic viewpoint, such words of criticism as have been uttered, or any other words for that matter, have little meaning until we reinterpret their acquired dictionary definition, in relation with the subjective context, within those who now use the words. A phonograph, a parrot, an imbecile, a lunatic, a moron, a metaphysician, a clergyman, a philosopher and a scientist can all be made to affirm, or disaffirm, a belief in the psychoanalyst's overemphasis of sex. However, from the mere declaration itself you get little or no information as to the mental content, if any, represented by the words. In other words, the psychoanalyst is little concerned with the words of such criticism, and puts all his emphasis upon the psychological how and why of their being used. The words of the criticism are mere symptoms, which can be adequately understood only in relationship to their entire subjective context, especially the past personal psychological experiential causation for their use.

It is of course possible that the quoted criticism is determined quite exclusively by the inductive use of objective considerations and data, or of subjective data consciously projected and impersonally viewed. But it is also possible that such a criticism is all but wholly determined by unconscious subjective factors. If so, then it is even probable that the criticism is a mere psychoneurotic's wishfulfilling phantasy, constructed as if for a mask with which to conceal an unconsciously determined and more or less morbid sexual obsession. I will suggest some of the methods by which a psychoanalyst might proceed in order to decide to which class any given critic's judgment may belong.

The psychoanalysts maintain that their claims about sex are the product of a new method of observation, and not a mere logical inference from a common stock of previously known material. To them it seems quite childish to quarrel about the results of their method, if there is no understanding or criticism of the method itself (1). If any of the critics are really objective and scientific, they would understand the psychoanalyst's claims as a challenge of method. Not one of the critics of psychoanalytic theory has found it convenient to criticize the psychoanalyst's methods of observation, or to exhibit his own intellectual method for comparison, as a competition in the relative maturity of intellectual methods. Hence we conclude that the critics are not functioning on an objective and scientific basis. This inference is further confirmed by the fact that the critics are content to make logical argument and a special plea in support of their preconceptions of what the truth about sex ought to be. Most of the time this appears to psychoanalysts as if it were a vindication of a psychoneurotic compulsion.

As a result of extended psychogenetic studies of emotional disturbances, the psychoanalysts invariably

find that the preadolescent and prepubescent sexuality plays an important but unconscious rôle in the causation of the emotional instability. In this connection the critics of psychoanalytic hypothesis have been challenged to produce, even a single case of psychoneurosis which, in the light of a psychogenetic disclosure, fails to reveal such determining sexual component. So far as I am informed, no such case, thus investigated, has ever been produced by the critics. Again we conclude that their criticism is not objectively nor scientifically conditioned. The suggested alternative is that such criticism is a mere wishfulfilling phantasy, brought into being by the necessities of a psychoneurotic's unconsciously determined emotional defensive necessities. Psychoanalysts may still be wrong, even though their present critics are entitled to no credit.

In one sense it is perfectly true that the psychoanalyst overemphasizes the importance of sex. It may be said that psychoanalysts specialize on those emotional disturbances centering in sex. Accordingly they overemphasize sex, in the same way in which an astronomer gives relative overemphasis to the movements of heavenly bodies, in comparison let us say with his interest in sociology or embryology. But it is more or less evident that this is not quite what the critics of psychoanalysis mean. We suspect that most of such critics mean to reproach us, and the mere selection of sex as a specialty cannot well serve as a reproach. Since our method of observation is also passed without criticism, the conclusion is forced upon us that what is objectionable to our critics is the psychoanalyst's whole attitude of mind toward sex, even more than the tentatively formulated products of his research. So we come inferentially to the conclusion that perhaps the criticism of psychoanalytic hypotheses is determined by a psychoneurotic's fearful resentment of a method which threatens to uncover his defensive mechanism, and to depreciate its moralistic mask. Perhaps the same psychological facts may be expressed as a psychoneurotic's resentment of his inability to maintain an imperturbable calm, in the face of a perfectly frank, public sex discussion, conducted in actual scientific dispassion.

However, there is something more to be said in justification of the critics. The psychoanalysts, on the whole, are concerning themselves primarily with the cure of functional disorders of the nervous system, and they find, as a fact of observation and not as a logical inference, that in such disorders there is always involved some psychogenetic sexual factor. That finding may be corrected by more and better observation. It can not be corrected by pure logic, nor by special pleas, or question begging, moralistic epithets, such as are used in the justification of popular sexphobia, masquerading as moral superstitions. Let us contemplate just a minute what the facts of life are, and see whether we cannot, even by logical processes, give some support of probability for the claimed facts of the psychoanalyst's observation.

Assume now, that the organism can be so viewed as to exhibit trends that can be labelled as life promoting and death promoting, which are both at work in all of us. As we look around us in times of peace, we can find little obvious emotional disturbances which give evidence of originating in the ordinary emotions which centre around selfpreservation. This is so because here our adjustments are relatively easy to make, in that they are relatively free from environmental interference. When there is no war, there is for most of us no such great anxiety, as there presumably was with the primitive man who had great difficulty in wresting his food supply from nature. For most of us, in our youth, that is now pretty well taken care of. It is quite different with the sexual impulses. Here, at least from early childhood until about twenty-five, external powers of coercion tend to enforce upon us biologically or psychologically unwholesome sexual lives. Even after marriage, economic factors and ignorance often prolong the difficulty. The primitive man, on the contrary, found it easier to live out, and to fully act out his reproductive impulses. We do not. It would therefore be very strange if the emotional disturbances, which the psychoanalysts are called upon to deal with professionally, did not have practically all of the time some important involvement of the emotions which centre around sex.

Psychoanalysts also find it to be quite accidental if we live even approximately wholesome sexual lives. Also: the emotional tones and values with which we come away from our earlier encounters with the sexual problem become the dominant emotional tones and values with which we are compelled to approach every other problem of life. In other words, if we become unduly impressed with fear, with shame, with uncertainty, doubt, or anxiety, or with calm confidence and optimism, because of the way in which we have managed our sexual impulses, then we unavoidably carry such dominant feeling tones and values into every other activity of our lives. Because of the relatively abnormal intensity which is imposed through social taboos and its resultant ignorance and socalled moral distortions, and the compulsory unwholesome living, the erotogenetic and more or less morbid valuations become the dominant characteristics with which we approach all the other problems of life, precisely because these habitual emotional attitudes have become the dominant affective essentials of our character. Even as a matter of mere logic it can therefore hardly appear otherwise. However, with the psychoanalyst this conclusion is based upon observation and not upon such logical inferences.

Another subdivision of the criticisms, which say that the psychoanalysts overestimate the importance of sex, rests upon our claim that there is such a thing as preadolescent sexuality. Perhaps you can achieve something of the feeling of probability if you remember that the Freudians consider that the human animal is an organic unity. Adolescence and pubescence produce nothing entirely new. They are but the fruition of processes that have been going on more or less unconsciously, from long before birth. Of course none of us will ever become fully conscious of all the factors and relations of our development. Psychoanalysts only insist upon the desirability of our enlarging our consciousness of these matters. Now then, the Freudians find, as the result of their observation, that this preadolescent "sexuality" has its own manifestations, its own experiences, develops its own sense of values, emotional tones, and ideational associations and reaction patterns, and so fixes the preparedness with which young people face the storm

and stress of pubescence and of adolescence. It is precisely because the infantile and childhood sexuality does that, that it also measurably predetermines how we go through it, and how we come away from it. So the preadolescent sexuality is, from the psychoanalytical point of view, a very important thing in the development of personality, and is one of the things which, in the near future, educators and parents will perhaps give a predominant place in the development and education of future generations. It is in this preadolescent sexuality that we find the important determinants for our later unconscious mentation.

Upon this unconscious mentation is based another criticism of psychoanalysis. The Freudians find, as the result of their investigation, that only a small percentage of the actual effectively working impulses are conscious to any of us, especially as to the subjective contribution to their determinants, unconsciously coming from out of our preadolescent eroticism. The great mass of the determinants for our conscious thinking and our actual conduct has, among the now unconscious data, most of our psychological past. Only a small fraction of this is any part of the conscious considerations at any time, especially when we are called upon to act or to consider a new problem.

Out of this concept, of the large unconscious factors in our thought and action, comes the psychoanalyst's theory as to the reconstruction of the personality. He assumes that every one's personality is the inevitable consequence of the entire psychological past. If you find yourself unhappy, if you find yourself inefficient in making your ordinary social or economic adjustments, the changeable determinants must be found primarily in that psychologic past, and all remedial measures must begin with the enlargement of our consciousness thereof and of the relationship of our past with the difficulties of the present, and the better coordination of all this according to maturer intellectual methods.

So far we have seen only those logical considerations which may make the psychoanalytic theory look a little more probable and so stimulate a favorable curiosity toward the matter of getting a first hand acquaintance with it, by submitting to a psychoanalytic discipline. Let us return to the critics. The critics of psychoanalytic hypotheses often assert that Freudians see in human nature nothing but sex. Thus the critics show their own sexual obsession. If they were not so much obsessed by the necessity (perhaps an unconscious urge) for selfprotection against a shameful, fearful or anxious attitude toward their own lewdness, more of them would have discovered that Freudians have repeatedly said that the libido or human energy expresses itself objectively and predominantly through two impulses. The first was characterized as the ego impulse, the impulse that makes for selfpreservation. The second is the sexual impulse, which makes for race preservation. The pursuits induced by the food hunger and sex hunger are among the more conspicuous manifestations of these two impulses.

Since Freudians have gotten farther away from the descriptive method, and talk more in terms of natural processes, sex becomes quite incidental. Then we see only conditions and behavior that make for a fuller and maturer psychological life, and those other conditions and the resultant behavior, which promote regression from a psychological toward a biochemical mode of functioning. The end product of this deterioration means the death of the human organism. When we view the psyche from the standpoint of an evolutionist who is studying the mechanism of a behavioristic subjective process, sex becomes a mere incidental conditioning factor. But there is another reason, perhaps, why the critics can not see this. They have a psychologic compulsion which makes for being easily misled. They need the soothing effect of finding and discrediting in others, those things which exist primarily in themselves, and about which they act, chiefly through unconscious mentation, as if they were endeavoring to conceal the same from themselves as well as from others.

What then is the psychoanalyst's conception of a scientific attitude toward sex problems? First of all one must be as free from emotional disturbances over every possible manifestation of sex, as the best poised astronomer is free concerning theories about the movements of the heavenly bodies. When dealing with the subject of emotions centering around sex, this unemotional viewing of sexual phenomena is doubly important, because doubly difficult of achievement. When emotions and their unconscious determinants are the subject matter of observation, one's predispositions find less ready means for checks and corrections than are at the command of the astronomer.

From the psychoanalyst's viewpoint this comes with peculiar force because he finds the determinants of our predispositions find their roots largely in infantile and childish experiences, which now constitute an important part of our unconscious mentation. Among these factors the preadolescent and prepubescent sexual development may be controlling. Because of such facts many psychoanalysts assert that no one is really competent to apply, or to criticize psychoanalytic hypotheses, until after they have become conscious of those determinants of their behavior and thought, which usually work below the surface of consciousness. In other words one's relative competency depends upon the relative degree to which that part of our mental life which usually works below consciousness has been made conscious, by submission to a Freudian psychoanalytic discipline or otherwise.

A second standard of efficiency is the relative degree to which the unification of one's interest has proceeded toward an obsession with mature intellectual methods, as a means of promoting our own well being and better social adjustments. It is only according to our relatively wholehearted devotion to, and adequate understanding of what may be meant by the subjective aspects of the maturity of our intellectual methods, that we can efficiently and happily make those coordinations which will operate as checks and correctives to the former unconscious controls of our psychic life.

For many minds there is another rock of offense in psychoanalytic presuppositions.

The psychoanalyst, following the physicist, quite consciously proceeds upon a similar presumption of natural law, and of a rigid psychologic determinism. Again, the object of his research is to discover ever

more of the hitherto unconscious, subjective, conditioning factors of our psychologic imperatives, and a growing clarity in his vision of the subjective aspect of our psychologic processes. If the psychoanalyst has reached a stage of development in which he is able to act in approximate harmony with the hypothesis of a complete and rigid psychological determinism, he will have outgrown all moral values and judgments, even about sex. No psychoneurotic can be comfortable without a moralistic rationalization of his erotic compulsions. The essentials of the psychological factor are the same, whether the moral creed is conventional or unconventional. From this viewpoint there is no necessary implication of progress in the substitution of new morals for old. Whether any progress is to be inferred under any circumstances, does not then depend upon our approval or disapproval of any particular moral creed. Intellectually we are alike in our indifference to all moral creeds. We may still have a feeling-preference for some line of conduct, but we have become too objective to impose our desires upon the other fellow as his moral duty. Neither do we glorify our subjectivism, when we become conscious of it. On the contrary we at once look for those checks and correctives, required by our conception of mature intellectual methods. This nonmoral attitude is offensive to most psychoneurotics, because they cannot easily get along without a moralistic explanation and glorification of one of their irreconcilable erotic trends. Their aversion will be as intense as the subjective conflict of impulse is acute.

Since some of us deprecate *all* moral values, and esteem all moral dogmas as useless, we never find any real psychosocial progress to be achieved through moral appeals. Indeed it is precisely because all moral appeals are unconsciously and subjectively conditioned, and are emotional in their nature and effect, and so tend to intensify, glorify and perpetuate the infantile method of thinking through and for our feelings, therefore all moral appeals, in so far as they are effective, become a hindrance to the maturing of our intellectual methods. From this point of view, we consider that all real individual and social progress can come only through means which must include the following: 1. Minimizing the influence of moral sentimentalism; 2, outgrowing the moralistic conflict of impulse, which is determined by unconscious factors, and appears as both a cause and an effect; 3, by the outgrowing of our emotional need for moral creeds, and other circumstances, by the means and toward the end of achieving mature intellectual methods, even as applied to problems of sex. What I mean by mature intellectual methods cannot be told within the limits of this essay.

When we have reached such psychologic maturity as I have in mind, we no longer regulate our sexual lives according to the conventional moral creeds of Mrs. Grundy, nor according to any code of the psychoneurotic sex reformer, not even the radical sex reformers. Now, with a considerable knowledge of Nature's psychoevolutionary processes and conditions, we live the whole of our lives so as to achieve an ever larger selfunderstanding, to the achievement of a growing poise and efficiency in social adjustments; all of which is again related to a maximum acceleration of the further maturing of our intellectual methods, in short of our psyche. Only so can we then hope to increase humanity's real comfort and satisfaction in life. In this process of maturing, the emotions which centre around sex are found to be a very important factor of control. If you now get any glimpse of what we are driving at, your opinion as to whether or not we overestimate sex becomes immaterial.

Herpes Zoster with Unusual Prodromal Symptoms*

With Report of a Case

SAMUEL WEISS, M.D., F.A.C.P.

New York

Recently, (1) Blanton reported a case of herpes zoster simulating nephrolithiasis, occurring in a female, aged fifty-two, with history of pain over and below the tenth rib posteriorly. This attack simulated intercostal neuralgia and nephrolithiasis. Several days later a herpetic eruption occurred which cleared up the diagnosis.

Case.—Mrs. S. R., aged fifty-seven, menopause ten years previously, was first seen by me on September 17, 1925. There had been a sudden attack of pain and burning sensation on the left side from the midback radiating down to the groin; also complained of a burning sensation on voiding urine. Codeine and other sedatives were of little benefit in relieving symptoms. X rays taken previously were negative for kidney stones. There was present tenderness on palpation in the epigastric region and lower left quadrant. The blood pressure was 150 systolic, 99 diastolic. The urine was negative. Colonic irrigations were advised.

The patient was next seen on October 28, 1925. Colonic irrigation gave her some relief. Urine examination was negative.

The following day the patient felt worse. On November 30th, urine examination showed faint trace of albumin, many epithelial cells, few pus cells, occasional red blood cells, many urates and uric acid crystals.

The patient's diet was changed and medication given to overcome the kidney irritation which was

*Presented before the Society for Clinical Study, New York, on January 26, 1926.

FIG. 1.—Anterior view of patient S. R.

thought to be due to a gouty or uric acid diathesis. Little improvement was shown.

Urine examination on December 4th still showed a faint trace of albumin, many epithelial cells, few white blood cells; red blood cells and urates; no uric acid crystals seen.

Two days later the patient complained of an itching sensation on the abdomen and noticed several small blisters. The next day these blisters increased in size and also a number of them appeared on her back. When seen on December 7th, the patient presented an eruption of herpes and itching, but otherwise the patient said she felt better. Urine examination showed a faint trace of albumin, many epithelial cells and a few white blood cells.

On December 13th, the eruption of herpes was more marked; condition was much improved, burning less, but itching about the same. Her radiating pain had completely disappeared. Urine examination at this time showed negative findings.

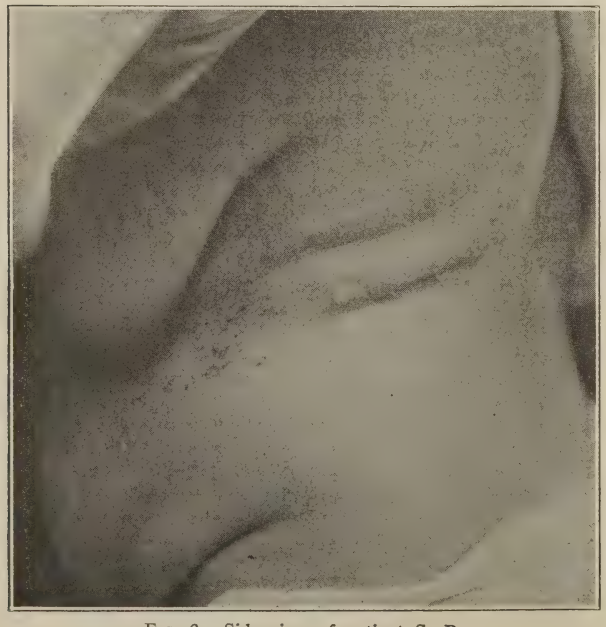

FIG. 2.—Side view of patient S. R.

SUMMARY

1. In this patient the pain and attack lasted for three months before the eruption of herpes occurred. When first seen the diagnosis was suggestive of intercostal neuralgia, nephrolithiasis or hypochondriasis.

2. Urinary findings were suggestive of kidney disease.

3. The eruption of herpes with the unusual prodromal symptoms, plus the urinary findings, makes one think of a gouty or uric acid diathesis as evidenced by the clearing of the urine under proper diet, medication and the relief of symptoms on the eruption of the herpes.

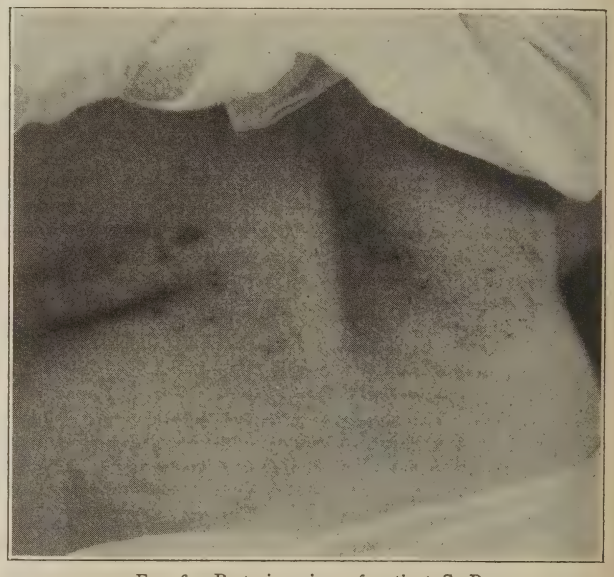

FIG. 3.—Posterior view of patient S. R.

Note: Since submitting this article the author has had two other patients with the same prodromal symptoms and relief after eruption of the herpes.

35 EAST 66TH STREET.

Action of Light on Codliver Oil.—P. R. Peacock (*Lancet*, August 14, 1926) states that exposure of normal cod-liver oil to any source of white light of sufficient intensity results in the following changes: 1, The normal bright golden fluorescence of the oil progressively disappears, this effect being termed "delumination." 2, Before full "delumination" occurs the oil fails to give the arsenic chlorid test for vitamin A. 3, Fully "deluminated" oil, when kept for some months in the dark, slowly regains much of its fluorescence, but the vitamin A appears to be permanently destroyed. 4. There is a change in the absorption spectrum corresponding with the change in the fluorescence of the oil. As "delumination" proceeds, so the transmission spectrum extends into the ultraviolet region; as fluorescence returns there is a proportionate return of the absorption spectrum.

Heart Disease*

JOHN WILLIAM SHUMAN, M.D., F.A.C.P.
Los Angeles

Heart disease is a prominent cause of disability and death. It is frequently overlooked, and also diagnosed when not present. Many patients think they have heart disease if they have a pain in the chest, and many physicians think heart disease is present if a murmur is heard in the precordial region. The three principal diseases of the heart are, endocarditis, myocarditis and pericarditis.

Endocarditis is always infectious in origin; most often streptococcic; and too frequently results in valvular disease of the heart—the mitral and aortic valves usually the ones affected. The reason it often passes early recognition is that it is not suspected. A typical example is that of a doctor's three year old daughter who was just recovering from bronchopneumonia and was running an unexplainable fever and fast pulse. Consultation brought out the diagnosis of endocarditis, much because all other findings were negative. Cardiac sounds were not instructive. The patient died and autopsy found "infective proliferative endocarditis."

The first opportunity you get to listen to the heart of a dying person, do so, then examine that heart after death and see if your ear told you correctly. Heart clinicians who have the habit of checking up their findings after death have had remarkable lessons and found out often they were wrong.

One reason we are so anxious to clear up all foci of infection, such as the teeth, tonsils, gallbladder, and other locations, is that there will be less likelihood of a lethal pathology, e. g., endocarditis, developing early in life. Many patients recover with valvular insufficiency and the myocardium compensates, and results in hypertrophy of the heart. Later myocarditis (which pathologically may be of several types)—results in dilatation (heart failure). If compensation takes place the patient recovers for a period of more or less duration, depending on many things.

There are four causes for socalled enlarged heart, First, focal infection (socalled rheumatism), the valvular disease of the heart just described, in which instance the transverse diameter is increased—the P.M.I. to the midclavicular line or outside it.

Second, hypertension, usually giving rise to the "hypertensive-cardio-renal-vascular-disease syndrome." Heart disease always causes renalopathy, and *vice versa*. So that in many instances of fully developed terminal anasarca both heart and kidneys are so diseased that we cannot decide which was primary and which secondary—something like the "hen and egg conundrum."

Excessive wear and tear does affect the heart. The best example is the degenerative myocarditis seen secondary to toxic adenomatous goitre. Be on the outlook for toxic thyroid disturbances early. Paroxysmal tachycardia should lead one to suspect it.

Third, syphilis, which usually shows manifestations in and about the semilunar valves, with aortitis, aneurysm, and other conditions.

Fourth, pericardial effusion, which may be serous (excess of the normal fifty c.c.), serofibrinous, seropurulent, fibrinous or purulent, or other forms.

Paracentesis of the pericardium is not a dangerous procedure if done when necessary and carefully.

Percussion is a method with which one can fool himself easily. Always use the fluoroscope or an x ray plate or both to check up the size, position, and shape of the heart and great vessels.

Functional cardiac rate disturbances are the different arrhythmias. The one best understood is auricular fibrillation, in which the auricular ventricular bundle of His does not impart the impulse correctly as to time, causing disorderly action of the heart (D. A. H.). Patients frequently come to the doctor mentally disturbed by the fact that their "heart misses a beat." Do not be alarmed at this or make a greater hypochondriac out of the patient by telling him, "it means death!" Examine carefully, observe diligently, clear up as much real and imaginary pathology as you can without making the patient worse and you will help.

Cardiac failure may be early or late. The late with generalized edema, prostration, albuminuria, and other conditions is so easy to recognize that we need not discuss except a word as to treatment—which is rest and elimination. It is the early that is seldom recognized. Its two chief signs are shortness of breath and pain. Shortness of breath is complained of upon exertion—perhaps in hurrying for a streetcar, or may be at the height of digestion following breakfast. It may be during or following a fit of anger. Pain may be from slight to severe, may be in the precordium, the left shoulder or down the left arm, in left neck and head, or in the left upper back around the scapula.

These two subjective symptoms call for our keenest interpretation. A thorough, painstaking, physical examination will find other things to warrant the diagnosis of heart disease (myocarditis). The individual is one who has or has had focal infection, led recently a sedentary life, (overeating, underexercising) and is now paying the price.

A test of the myocardium as to fitness may be done by taking the pulse rate, then having the patient jump up and down twenty-five times, lie down, and count the pulse every minute. If the rate does not in five minutes equal that prior to the exercise myocardial weakness is marked. Treatment: rest in bed, digitalis, quinine, morphine.

The cycle of mitral insufficiency goes something like this:

1. Hypertrophy of left ventricle and dilatation of the left auricle with
2. Passive congestion of lungs.
3. Hypertrophy of right ventricle
4. Dilatation of right auricle
5. Tricuspid insufficiency resulting in,
6. Passive congestion of the liver resulting in the scarring of the liver which may be nutmeglike, brown atrophy, and other conditions causing ascites.

Practical Therapeutics

The Treatment of Narcotic Addiction by Narcosan

ALEXANDER LAMBERT, M.D.
and FREDERICK TILNEY, M.D.
New York

In the summer of 1926 Commissioner of Corrections of New York city, F. A. Wallis, invited a group of physicians to visit the penal institution on Riker's Island, and pass judgment on a treatment for narcotic addiction which had been brought to his attention, and which had been tried on a small group of men. This group of addicts were in excellent physical condition, and in appearance showed no evidences of their previous narcotic addiction. They claimed they had slept during their treatment without other drug, and that they enjoyed their physical work afterward.

In spite of the evident crowd psychology, it was clear that a treatment which left the patients in such excellent condition was worthy of further investigation.

Later in October, at the request of Commissioner Wallis, a meeting was held to discuss the treatment, and the possibility of a further trial of its value.

The treatment advocated was the use of narcosan, a substance made by A. S. Horovitz, a biochemist, not a physician. This substance had been used successfully for narcotic addiction, and had been the subject of considerable controversy, but with no comprehensive test under proper conditions to settle its value. A strong and valid argument against it at this time was that it was an unknown substance, and under the objections to secret remedies could not be used.

It was suggested to Mr. Horovitz that he patent narcosan, through which act its composition would become known. Mr. Horovitz assented, and immediately patents were applied for at Washington. This places narcosan on the same basis as thyroxin, the active principle of the thyroid gland as patented by Kendall of the Mayo Clinic, or of salvarsan, an arsenical preparation patented by the chemist, Ehrlich, neither of these chemists being physicians.

The patent papers show that narcosan is a solution of lipoids, together with nonspecific proteins, and water soluble vitamines.

The lipoids are obtained from soy beans and cotton seeds, by extraction with hot alcohol; the vitamines from plant seeds by percolation with saline solutions; the nonspecific proteins from alfalfa seeds, or Hungarian millet, by extraction with highly diluted hydrochloric acid. Equal parts of these three solutions are mixed together to form narcosan. The proteids extracted by acid are used instead of those obtained by alkalies, as the acid proteins are nontoxic, while some of the alkaline proteins are highly toxic. The hot alcohol extracts both fats and lipoids, the fats being separated from the lipoids by a process of saponification.

The lipoids in narcosan have the chemical affinities and reactions similar to those of sphingomyelin, and as for sphingomyelin, the formula cannot be exactly given. Levene and Rolf (1) in their review of the phosphorus containing lipoids, state that but three of these are known, lecithin, cephalin and sphingomyelin. Many other lipoids, when originally separated, were supposed to be new individual substances, but have been shown to be fractions or combinations of the three just named.

Sphingomyelin yields by hydrolysis phosphoric acid, two bases, choline and sphingosine, and two fatty acids, but while the composition of it seems to be agreed upon, the allocation of its atoms in forming its constitution is still under discussion (2), and until it can be made synthetically, its exact structure cannot be definitely stated.

The exact formula, therefore, of the lipoids in narcosan cannot at this time be more definitely stated.

It has been independently proved by several chemists that narcosan does not contain morphine, heroine, codeine, nor chloral hydrate, nor does it contain any alkaloid, nor habit forming drug.

The theory on which narcosan was compounded was that of Myer and Overton regarding anesthetics that the "Narcotizing substance enters into a loose physiochemical combination with the vitally important lipoids of the cell." (3)

The theory of the action of narcosan in the body is that narcotics, such as morphine, call forth in the body certain protective substances to neutralize them. If the narcotics be suddenly withdrawn, and not given, these neutralizing substances are themselves toxic to the body. The lipoids in narcosan neutralize these toxic substances in place of the narcotic.

After seventy-two hours, because the withdrawal symptoms are over, these neutralizing reactions have ceased, the lipoids are then continued to replace the depleted lipoids in the body. The nonspecific proteins of the narcosan solution are added to stimulate the blood forming tissues. This is a theory which scientific investigations must prove or disprove.

In this regard it is interesting to note that the work of van Leeuwen (2) confirms the idea that the lipoids exert a definite influence on the action of alkaloids in the body. He has shown that cephalin augments the action of pilocarpine, while lecithin inhibits this action of cephalin on the pilocarpine.

He has also proved that the serum of men and animals inhibits the action of cocaine, without destroying the cocaine, and has further shown that lecithin possesses the same inhibiting effect on the cocaine. In an interesting discussion (3), he holds that this effect is produced by a physical combination in the adsorption of the drug, and is not due, as many others believe, entirely to the destruction of the drug by the liver. Other workers have found that animal tissues render inert other alkaloids such as digitaline and strychnine.

But the work of Greenfield and Pellini shows that up to the present time, though sedulously sought for by many investigators, these neutralizing or protective substances to morphine have not been proven to exist in the blood of human beings or animals tolerant to morphine. Nor was any toxic substance found present in the blood as a result of morphine habituation. The validity of a theory, however, of how narcosan acts is a question aside from its value and effectiveness as a remedy for narcotic addiction.

Commissioner Wallis was extremely anxious to find some form of treatment which would replace the socalled "cold turkey" method, or ordinary withdrawal method practised in the penal institutions in New York. He was anxious to try narcosan as an effective and useful treatment to help solve part of the narcotic problem with which the penal institutions in large cities in this country are faced.

A special ward was set aside in the Correction Hospital on Welfare Island for men, and quarters at the other end of the building for women, under Supervising Warden H. O. Schleth. The treatment was begun on March 30, 1926.

Some 219 men and 147 women have been given this treatment. It has shown itself to be of unquestioned value, producing a successful withdrawal of the drug in a few days, in some instances with but little discomfort, and in all instances with less suffering than the ordinary withdrawal method. The patients sleep without hypnotics of any kind during and after their treatment, and at the end of a few days are hungry, and digest easily all that their renewed and voracious appetites cause them to take.

The treatment is easily carried out with much less detail than with the belladonna treatment, and with no delirium as in the hyoscine treatment, and leaves the patient free from depression, and, as must be emphasized, with a returned ability to sleep.

The type of patients were those found in the penal institutions of a large city, the petty offenders for small crimes, who were addicted to the use of heroine and morphine, or those selfcommitted who have been sent by the courts to rid themselves of their addiction. In a few of these patients the addiction has been of short duration, in many of several years, ten or fifteen years' duration, others had been even thirty or forty years steadily addicted to some narcotic. It was strikingly noticeable that many of these patients began by smoking opium. They then took to opium by mouth, or morphine by hypodermic, and then turned to heroine, because of the difficulty of obtaining morphine at present. Sixty-three per cent. of the men, and eighty-four per cent. of the women were using heroine, sixteen per cent. of the men and twelve per cent. of the women used morphine, seventeen or eighteen per cent. of the men were using cocaine with their heroine, only one man combined cocaine with morphine; of the women, only two used cocaine, one with heroine, and the other with morphine. Heroine and morphine combined were used by twelve per cent. of the men, and by two of the women.

As in all prison statistics, only a small percentage of these patients gave sickness, or pain, as the reason for their starting the addiction. The majority drifted into it through the temptations of their environment. Many who were taking heroine volunteered the information it was the most easily obtained narcotic, and that in other parts of the country they would take morphine instead of heroine, as that was there the more readily obtained of the two.

All these patients previous to admission to the narcotic ward had had their baths, their thorough investigation as to whether or not they were concealing any narcotic on themselves. On admission to the ward they were given a capsule composed of:

Hydragyri chloridi mitis	gr.i	gm. 0.06
Ext. Colocynthidis	gr.iii	gm. 0.18
Ext. Euonymin	gr.s	gm. 0.06
Resinae Podophylli	gr.ss	gm. 0.03
Capsici	gr.ss	gm. 0.03
Pulv. zingib. } aa Strychninae sulph. } aa	gr.1/60	gm. 0.001

This was followed three or four hours later by a dose of epsom salts; as soon as their bowels acted they were given one c. c. of narcosan hypodermically. This was given intramuscularly, in the muscles of the upper arm, or in the shoulder at the back of the arm. These narcosan hypodermics are given thus every four hours for the first twenty-four hours, then every six hours for three days and nights, and then every twelve hours for three days and then once a day for about ten days, or until the patient has had about forty injections. No injections of morphine or heroine must be given. If these narcotics are given intense distress, nausea and vomiting, headache, and a sense of benumbing collapse is produced. In fact, the administration of morphine or heroine can produce a serious collapse. If the patients succeed in smuggling in narcotics and take them, these symptoms soon are evident. The narcosan treatment is selfprotective against the patient indulging on the sly in narcotics. If patients are nervously collapsed from the sudden withdrawal of their narcotic before treatment begins, they should be given narcosan immediately to quiet them, especially the women, who are more likely to become wildly hysterical under these circumstances. This quiets them and then they should have their cathartics.

For the first twelve hours the patient becomes nervous and restless, he feels weak, and is likely to be troubled with twitching of his muscles, pain in the back, and headache, and often pain in the legs. As the narcosan is given to him he becomes less nervous, and if the patient is excessively nervous an extra dose of narcosan can be given him at the two hour interval. The majority of the patients do not sleep much the first night, not a few, however, do get short naps, or among some of the heroine takers, they obtain quite a little sleep. Some patients go through the entire treatment with hardly any uncomfortable symptoms.

In the next twelve hours the twitching and the nervousness continue, and patients are apt to have nausea and vomiting, and some have abdominal cramps and diarrhea. Some of these patients will have simply the nausea and vomiting, others will have only the diarrhea. When their diarrhea becomes excessive there is a diminution in the amount of urine passed. If the diarrhea is not excessive they begin frequently to show a diuretic effect, and pass an increased amount of urine. Many of them feel cold and are with difficulty kept warm, others sweat abundantly.

On the second and third night they begin to sleep

at short intervals, or obtain two to four hours sleep. After the second night the majority of patients say that they feel much better.

Often when vomiting other substances, these patients can retain fruit juices, such as of lemons and oranges, and it relieves the dryness of their mouths, and makes them more comfortable.

Among those who show a severe reaction are especially those with morphine addiction of long standing, these patients are likely to have severe abdominal cramps, their pulse becomes frequent, and even feeble.

In other patients the pulse becomes infrequent, dropping down below 50, but these do not have as much discomfort as those with rapid pulses. Those with slow pulses, however, do not seem to have as quick a reaction towards convalescence and recovery as those with frequent pulse rates. By the third night the patients are beginning to sleep better, and the symptoms are abating even in those who seemed previously severely ill.

They soon improve, and in the great majority of instances on the fourth day become comfortable. They acknowledge their physical craving for narcotics has ceased. By the fifth day their appetite begins to return, and they sleep more both in the daytime, and at night, and soon their appetites become excessive, and they are hungry, and continuously eager for food, especially sugar. The older patients, and those long addicted to morphine, convalesce more slowly, and complain of weakness although they sleep and have no pain nor narcotic longing.

During the treatment, if the patients are very nervous and uncomfortable, hypodermics of one sixtieth of a grain of strychnine, or even one thirtieth, can be given every four hours, or even every two hours as the patient's need seems to demand. If every three hours the patients are given thirty grains of bicarbonate of soda dissolved in water, and made to drink it, their vomiting, and their diarrhea is much less, their abdominal cramps are markedly diminished, and they do not go on into the simulation of collapse that a few of them will do if the bicarbonate of soda is omitted.

We have tried many remedies to relieve their headaches, and other pains, and remedies to relieve their nausea and vomiting; aspirin and phenacetin and the other coal tar products do not seem to give satisfactory results, and the patients were better without them than when they are given.

The one drug that seems to relieve their nervous restlessness is the strychnine, and if the bicarbonate of soda is pushed, their discomfort during the treatment remains at a minimum.

Fear is a great element in these patients coming off of their narcotics, and the women are specially prone to become hysterical through fear. Another emotion is that of anger because no narcotics can be given. They emotionally cling tenaciously to their narcotic, and resent the deprivation. Many selfcommitted patients have committed themselves to reduce the necessary amount of their drug to be taken after they go out in order to obtain a renewal of their former pleasure in beginning their addiction over again. These resent bitterly the obliteration of their narcotic craving by the third or fourth day. If these emotions are quieted, and bicarbonate of soda is pushed regularly, their symptoms are much diminished.

Patients are not delirious as in the hyoscine treatment, thrashing around in a low delirium; they are not ugly and obstreperous, as in the slow reduction treatment; they are tractable, subdued and quiet, and soon appreciate that the hypodermics of narcosan relieve their symptoms, and they ask for an extra hypodermic from time to time.

These hypodermics do sting, and give a burning sensation, but when given straight into the muscle, and the place is rubbed previously, and the skin stretched, and not picked up and pinched between the fingers, and the place of injection rubbed thoroughly after it is given, this stinging and burning is much diminished in its severity, and in many persons ceases altogether. Before the giving of each hypodermic it is necessary to boil carefully the syringe and the needle, and when this is done there are no infections; if it is not done abscesses may occur. The needles boiled in dilute soda solution just previous to the injections, and kept in mineral oil, keep in excellent condition, and give no trouble. Old abscesses were frequently found in these patients, but when opened and dressed, they healed with more than usual rapidity.

In the early period of giving narcosan, the severity of the abdominal cramps in a few patients, the intensity of the nausea and vomiting and the simulation of collapse as similar to an abdominal perforation, but with Kussmal type of breathing, gave the picture of an acute acidosis poisoning. It was on this evidence that the bicarbonate of soda was used and pushed so vigorously, with such excellent results. One patient, a negress, thirty-six years old, who in two previous reduction treatments had had convulsions and serious collapse, nearly ending fatally, had intense pain due to intestinal spasm, with small frequent pulse and cold extremities, with unexplained dyspnea and collapse. In spite of vigorous stimulation, the patient died forty-eight hours after beginning treatment; this was the only fatality.

To ascertain if variations in metabolism occurred in the body during the treatment, before beginning the narcosan in nine patients the blood was taken on admission, and tested for urea nitrogen, uric acid, creatinin, and sugar, and the amount of carbon dioxide combined with the plasma. This was done during the five consecutive days of the treatment, during which the patients showed symptoms. The red cells and the hemoglobin, white cell count and differential counts were made simultaneously, and a twenty-four hour specimen of urine was gathered and analyzed.

In another group these same examinations were made for five days, beginning twenty-four hours after the narcosan was first given; in another group the examinations began forty-eight hours, and in still another group ninety-six hours after beginning of the narcosan, and continued for five days, as they were convalescing. This gave an idea of their blood chemistry during their withdrawal symptoms, and for the first nine days of their treatment, and of the leucocytosis and the differential count, and the changes occurring in the urine. These examinations of blood chemistry, urine and the blood counts were done by the laboratory of Dr. Frederick Sondern.

A month after the completion of the treatment,

after they were out of the ward, the blood sugar and the carbon dioxide content were taken again, in a group of nine former patients, to see if it had dropped back to normal.

These examinations in detail show as follows: the blood chemistry shows an uninfluenced normal of the uric acid and creatinin. The urea nitrogen averaged 20.2 mg. per 100 c. c. for those examined on admission before narcosan had been given and 18.7 for those examined in the first eight days of the treatment. It averaged 19.9 mg. for those examined in the first five days, but averaged 17.3 mg. in those examined from the fourth to the ninth day. The sugar content of the blood was high, averaging for those examined on admission before beginning treatment 123.3 mg. varying from 106.5 to 150 mg., and for those examined during the first nine days of treatment 147.5 mg. In the case of those examined during the first five days of treatment, the blood sugar averaged 134.8 mg., and in those examined from the second to the seventh day the sugar averaged 155 mg. This rise is due in some measure to the increased consumption of sugar on the sixth and seventh days, since after the fifth day of treatment these patients have an excessive craving for sugar. This desire for sweets lasted throughout their treatment. In two patients examined after ten days of treatment, the blood sugar averaged 168.6 mg., due doubtless to the amounts of sugar consumed. The blood for these tests were taken at 8:30 a. m. an hour after their breakfast, and the sugar content was probably influenced.

In nine patients examined during the first nine days the blood sugar averaged 133.4 mg. One month after all treatment had ceased the blood sugar of these same nine patients, taken at the same time one hour after breakfast, had dropped down to normal, and averaged 114.6 mg., varying from 90 to 135 mg. It is striking that only in one patient on one day when his blood sugar registered 150 mg. did any sugar appear in the urine. These twenty-seven patients examined varied in blood sugar content from 105 mg. to 210 mg. In sixteen of the 121 sugar examinations the blood sugar was above 180 mg., which is given as the usual threshold in normal persons beyond which glycosuria appears (1). Yet glycosuria did not occur in any of these patients. It would seem as if the narcotic inhibited the use of the sugar, rather than increased its presence in the blood, and when free from the narcotic, excessive intake of sugar, produces a high blood sugar, and a rapid consumption by the tissues occurs without sugar loss through the kidneys.

The carbon dioxide chemically bound by the plasma averages 57.8 c. c. for those examined in the first nine days of treatment. Many of these patients showed a low carbon dioxide of 46-48 or 50 c. c., averaging 53.2 c. c. in the eight patients examined on admission. On the following day after receiving narcosan, they showed 58-68-58 c. c. Others showed an increasing acidosis for the first three days of treatment, and then a sudden improvement. With the low carbon dioxide in some instances there appeared in the urine traces of acetone and diacetic acid for twenty-four to forty-eight hours. In nine patients whose carbon dioxide content averaged 55 c. c. during the treatment, varying from 38 c. c. to 76 c. c., one month later, after all treatment had ceased, the carbon dioxide content averaged the normal 70 c. c., varying from 64 to 76 c. c. The variation in the carbon dioxide blood content did not follow any definite relationship with either the increase or diminution of the urea nitrogen or sugar content in the blood.

These narcotic patients were not excessively anemic, although the hemoglobin was not higher than 80, it was not lower than 70 in any of those examined. The lowest red cell count was 4,300,000, and the highest 4,890,000. During the treatment there was a slight leucocytosis of polymorphonuclear leucocytes. The leucocyte count varied from 6,800 to 16,200 and the percentage of polymorphonuclear cells varied from 60 per cent. to 83 per cent. usually being about 70 per cent. When leucocytosis was present the leucocytosis was not present until after the administration of narcosan.

The twenty-four hour specimens of urine were small in amounts with high specific gravity, being concentrated from excessive diarrhea. In some patients the urine was negative throughout the treatment. Usually there was a slight trace, or trace of albumin, a slight excess of indican, a few pus cells, occasionally a few hyalin casts. In a few instances there were a few red blood cells for one or two days, and then these ceased to appear. Often there was an excess of oxalate of calcium crystals. As has already been stated, rarely a trace of diacetic acid, and not infrequently a trace of acetone, but sugar was present in only one specimen of one patient, whose blood sugar on that day was 150. No bile pigments appeared in any specimen of urine examined.

The previous venereal history of these patients was entirely unknown, but the frequency of a few pus cells noted in the urine may not have been due to narcosan.

The convalescence of the patients under a daily injection of narcosan is interesting to any one accustomed to narcotic addicts under treatment for their addiction. The narcosan patients have a voracious appetite, are always hungry, especially for sugar, and unlike after other treatments can digest all they eat on the fifth or sixth days of this treatment without any digesive disturbances, and without any recurrence of their withdrawal symptoms. The natural habit of sleep returns to them sooner than after any other treatment. They rapidly improve in color, and rapidly put on weight on the regular prison fare. They acknowledge that they "don't think of the dope." Not infrequently patients sweat at nights, a few excessively, which ceases immediately on the cessation of narcosan. A few showed a blotchy, urticarial rash, appearing fifteen or twenty minutes after narcosan injection, and disappearing in about two hours; a few showed a fine proteid rash which soon disappeared. Three patients showed an internal strabismus, which disappeared entirely before they left the ward. These patients crave in convalescence fresh air and sunshine and are eager for muscular action and work. They do not hesitate to mount on ladders or scaffolds, they are sure of their equilibrium, a normal condition, which those taken off narcotics by the reduction treatment rarely possess.

How many of these 366 patients will relapse and return to the narcotic and again appear in the Work House is absolutely unknown, and incalculable; it can not be estimated for at least eighteen months.

Thus far, over six months, only one patient, a negress, has come back to the Work House. This patient stated that she had no desire for her drug, but it was a perfectly good method of obtaining pleasurable sensations, and she did not intend to give it up. The question of relapse to narcotic addiction is a question of companionship and social environment, with their group customs and herd suggestions acting on psychologically distorted personalities. It is a social question to be dealt with after discharge. The question here investigated is purely a medical decision of the value of narcosan as a treatment for narcotic addiction. Narcosan is equally efficacious in the treatment of other narcotics, as alcohol and veronal. These last drugs do not have the withdrawal symptoms of the opium narcotics. The patients rapidly clear up mentally, and sleep during their treatment, and after twelve to twenty-four hours cease to demand their narcotics. They convalesce rapidly.

Skilled nursing is a necessity in carrying out any treatment for narcotics. We wish to make public acknowledgment to the nurses who so skilfully and successfully aided in this treatment.

Morphine.—M. A. Slocum (*American Journal of Surgery,* 40:4) advocates the preoperative and postoperative use of morphine, the former to prevent or lessen shock, the latter to prevent or relieve pain. Although it is generally accepted as an aid in preoperative use, its postoperative use is still a matter of controversy among many. The author finds that postoperative complications are little influenced by the administration of morphine since they occur many times in patients who have been denied morphine. Moreover, the drug in itself does not act as a cause of complications.

There would seem to be a great deal of evidence that morphine will prevent postoperative shock, if given in small doses and at proper intervals after operation. While part of the credit for the diminishing incidence of this tragic condition must be given to expert anesthesia and careful operative technic, no small part of it belongs to the morphine.

It is an accepted physiological fact that morphine is the best circulatory sedative that is known. It is then, a reasonable deduction that the drug will lessen the likelihood of postoperative hemorrhage, a condition that is seldom seen nowadays.

The statement is often made that because morphine lessens peristalsis its use is contraindicated after abdominal operations. To this rather dogmatic opinion I cannot subscribe. Since both anatomical and physiological rest are greatly to be desired in these cases, then a splinting of the bowel would appear to be a benefit to the patient rather than a menace. It is for just this reason that morphine has been found to be the drug *par excellence* in the treatment of peritonitis. Furthermore, since this latter condition is the most feared of all postoperative abdominal complications it follows that morphine, through its splinting action on the bowel, has much to do in preventing the spread of any infection that may be present.

Nonspecific Protein Injections in Chronic Arthritis.—W. Yeoman (*Lancet,* June 26, 1926) submits an analysis of fifty cases treated with a specially prepared typhoid paratyphoid vaccine made up in the proportions of two parts of Bacillus typhosus to one part of Bacillus paratyphosus A and B.

The summarized findings are as follows: 1. In the intravenous injection of vaccine we have a therapeutic agent which is capable of producing improvement in a short space of time in between eighty and ninety per cent. of all types of arthritis, and this improvement is maintained in between fifty and sixty per cent. of the cases. 2. The types which respond best are the acute and subacute where the disease is confined to the periarticular tissues—in these cases permanent benefit is assured in over ninety per cent. of the cases. Where the joints themselves are affected definite improvement occurs with arrest of the disease, but naturally bony changes cannot be altered. 3. If all possible foci of infection have not been removed the injections do not arrest the disease and the patient will relapse. 4. Though the reactions are severe the contraindications are few—disease of the myocardium, gross kidney disease, chronic alcoholism, tuberculosis and syphilis being the chief. 5. The most desirable reaction is that in which there is a rigor, sharp rise of temperature, quick fall, and profuse perspiration, and doses should be regulated to produce this. 6. In view of the proved ability of these injections to cut short an attack of rheumatic fever, the author pleads for an extended trial of this treatment in the hope that much invalidism from heart disease might be prevented. 7. The patients who do not do well are those in the menopause group of the chronic villous type, and those showing achylia.

Treatment of Beginning Mastitis with Local Autohemotherapy.—V. Rubeska (*Zentralblatt für Gynäkologie,* January 30, 1926) formulates the following specifications for autohemotherapy in beginning mastitis:

The injection of the patient's own blood should be made as soon as possible (within twenty-four to thirty-six hours) after the appearance of the first symptoms. The dose with the nonlocal application must be at least forty, but better sixty c. c. If the temperature does not fall to normal on the following day, the injection should be repeated, in that case possibly locally around the inflammatory focus. Otherwise good results are obtained with injections in the thigh, the technic of which is simpler for the physician and more pleasant for the patient. But it must not be forgotten that with the local injection of the blood a greater local concentration of the antibodies is obtained, so that a larger dose must be given when the injection is made into the thigh.

The Static Current in the Treatment of Inflammation*

WILLIAM BENHAM SNOW, M.D.

New York

The consideration of inflammation has been a classical topic in all ages of medicine. Now, as never before, the classification of types is more distinctive and the methods of treatment more successful with the progressive development of the science. There are two distinctive groups of inflammatory conditions, those designated by Adami as simple, in other words, those in which there is no infection, and those associated with a process of infection. There might be a third class added, namely, those arising from disturbed metabolism, and the inflammatory conditions arising from infection might be divided into two classes, namely, those in which the infection is located at the site of trouble and those in which the local condition is toxic, caused by an infection elsewhere.

INFLAMMATION DEFINED

Inflammation has been variously defined. Adami (1) quoting Grawitz (2) states that "inflammation, he holds, is the reaction of irritated and damaged tissues which still retain vitality. This definition has this great advantage, that, stating the cause, it clearly recognizes inflammation as a process and not as a state. The manifestations of this process under favorable conditions—where the region injured is a loose and vascular tissue, and where the injury is sufficiently severe or extensive—are redness, swelling, heat and pain; redness from the congestion of the vessels; swelling from the exudation of fluid and corpuscles from the congested vessels; heat from the increased amount of blood in the region, and pain from the irritation of the terminations of the nerves in the region. To these four signs may be added a fifth, disturbance of function, brought about by this departure from the normal condition of the region."

Adami (3) further states that "the increased temperature of superficial areas when inflamed is due, not to the production of heat in the part, but to the increased quantity of blood passing through it. When the congestion is so great that stasis ensues, there may be actual decrease in the temperature of the part."

Adami (4) also states "that the exudate varies in amount and in character with, a, the nature and intensity of the irritant; b, the condition of the organism, and c, the region of irritation. That while it undoubtedly augments the nutrition of the affected region, increased nutrition at the early stage of an acute inflammatory process would not seem to be of benefit or to play any important part. At a later stage and in chronic inflammation the increased nutrition possibly aids the hyperplasia."

PATHOLOGY

It will be seen here that the ultimate condition recognized by this eminent authority is hyperplasia. In other words, when stasis exists for a time hyperplasia is certain to intervene. It is, therefore, recognized as a fact not to be questioned that the effect of unresolved stasis is the establishment of hyperplasia. The importance of the resolution of stasis at the earliest possible moment is indicated in all cases of noninfected inflammation either as associated with the margins of lacerated tissue or in the tissues of a joint or other part resulting from a traumatic injury.

Exudations occurring in the synovial structures of joints following traumatic injuries of joints are particularly to be considered in this class, for the fluids which accumulate in these structures require prompt attention and removal in order to establish the reparative process as soon as possible after the injury or strain. Other inflammatory processes as occurring in organs or glands of the body, which are not the seat of inflammation, as of the liver, spleen, prostate gland and uterus, are likewise to be considered as inflammatory in character and requiring resolution or elimination of the exudations in those parts and elsewhere in joints and perineural sheaths arising from trauma or focal infection elsewhere.

The inflammatory processes of the various types referred to may be considered in practically one class as requires the removal of the infiltrating exudates and when caused by focal infection, coincidently curing the infection.

The treatment of these inflammatory conditions is a matter upon which various views have been advanced by authorities. Adami (5) in a short chapter devoted to treatment in his work on inflammation considers the subject as follows with reference to a "reaction in excess," which he states "is the excep-

*Read at the First Annual Meeting of the New England Association for Physical Therapeutics at the Copley Plaza Hotel, Boston, Massachusetts, on Tuesday, October 26, 1926.

tion, not the rule. At most we note in acute cases that one factor in the process may be unduly exalted as compared with others, so that the vitality of the tissues is imperilled—excessive hyperemia may pass on to stasis and necrosis, there may be excessive deposit of fibrin, and so on—and means, where possible, must be taken to regulate the process. Another group of cases would seem undoubtedly to be the series of sympathetic or referred inflammations, in which parts, whether surrounding the injured area, as in the case of the joints, or at a distance, but innervated from the same region of the cord, show the symptoms of an acute inflammation when they themselves have undergone no direct irritation. A knee, or an ankle, for example, which has suffered a relatively slight mechanical injury of the joint surfaces or ligaments, may rapidly present intense swelling and redness of the surrounding parts. Such in the absence of any treatment tends to bring about immobilization and physiological rest, but where recognized it may safely, I think, be dispensed with, provided physiological rest may be gained by other means."

In this statement he implies, of course, the use of retaining splints as of plaster. This method was followed in the early part of the Great War in the treatment of all cases of arthritis, but ankylosis occurred so frequently that the surgeons were brought to realize that the worst thing to do for an inflamed joint was to put it in casts. Even the open cases were treated by the open method in order that the joints might be mobilized. This definitely determined a new doctrine for the treatment of acute traumatic injuries of joints.

Adami (6) states further that "it is in these cases of excessive hyperemia tending towards stasis (as suggested to me by my colleague, Dr. G. Armstrong) and of referred inflammation, that the reduction of the hyperemia by the application of cold would clearly seem to be the proper practice. In chronic inflammation it cannot be said that there is any direct treatment. If fibrosis has occurred we cannot directly cause its absorption. We have, it is true, evidence that fibroid tubercles and fibroid adhesions may eventually disappear; we cannot bring about this result with certainty in any particular case. At most we can endeavor to improve the circulation in general, and by that and other means improve the vitality of the tissues and favor the removal of the irritant, as also by the employment of drugs, such as potassium iodide, we can strive to promote absorption. Electricity, active and passive movements, and massage are all useful auxiliaries. Vesicants, rubifacients, setons, and counterirritation have all been employed toward the same end."

Contributions of the most recent writers on the subject of the treatment of arthritis go little further than the method advised by Adami. Pemberton (7) states that "of great importance also in the restoration toward normal is the intelligent use of baking, hydrotherapy, massage and exercise. Agents that favorably influence the metabolism, such as arsenic and radium, are of great value, and the influence of systematic rest of the whole body may be a *sine qua non* of succesful therapy."

It would seem, therefore, that, from the presentation of the observations based upon the methods employed as suggested by Adami and the more recent observations of Pemberton, they are matters of no small consideration if their point of view represents the present status of the treatment of these cases by the orthopedist.

In a paper read by me (8) before the American Electrotherapeutic Association at Buffalo in 1901, I first called attention to a demonstration which I had made during the previous year in the treatment of a young man's hand, sprained in the gymnasium, when, in falling, he had sustained his body weight upon the extended right hand and sprained the carpometacarpal articulations. The swelling and pain in the hand on manipulation were so great that he refused to permit handling, and could not close or use the hand. The x ray disclosed the fact that there had been no fracture, and with an application for one half hour of the static brush discharge applied over the back of the hand where the swelling was considerable, during the application it very nearly disappeared. That result disclosed the fact that what we accomplish with the static modalities is the early removal of exudations, before hyperplasia, occurring with local inflammation, when arising from trauma or other causes. The only exit for such infiltration once in the lymph spaces is by way of the channels of circulation. The successive contractions induced locally in the tissues and muscle cells forced the accumulated cells on through the outlets, and the local swelling disappeared. The same treatment on the following day gave complete relief. To one who had contended for days and weeks with sprains, this was a revelation.

This was the first presentation of the subject before a national body and was the result of a previous experience of three years in the New York Postgraduate Hospital Clinic in electrotherapeutics and nervous diseases of Dr. William James Morton, in which I was at that time instructor. In the discussion of this paper it was acknowledged by Dr. Morton that prior to this time the use of electricity in acute conditions had not been generally recognized. The consensus of opinion had been, and is today with the neurologists and many others, that electricity should never be employed in the treatment of acute inflammatory conditions. Since the presentation of this paper, the sentiment has grown steadily in favor of the early treatment of every traumatic inflammation as well as of infection by radiant energy and high frequency modalities in the infections and static modalities in the noninfected cases.

Attention was again called to the importance of this principle in my work on *Static Electricity and Uses of the X Ray* (9) and again in my work on *High Potential and High Frequency Currents* (10) and in numerous other contributions I have made on the treatment of inflammation. Since the introduction of this principle, large numbers of physicians have demonstrated without question the validity of the claims that the static modalities will remove early induration, so establishing circulation with restoration of function in processes which are the seat of local stasis.

It seems, therefore, that every effort should be made as these facts are confirmed to advance the establishment of methods which mean so much for the relief of pain and suffering of conditions that cannot be so satisfactorily relieved by other means. It is true that when the congestion is such that stasis is established the use of diathermy and radiant light

and heat will not restore circulation. When a hard indurated area is once established, it is quite impossible to effect a restoration of circulation by the employment of these measures but the tendency is rather to increase the local congestion by urging more blood into the already obstructed field. As set forth in my early exposition of this subject, the static modalities are practically the only electrical methods that will effect such resolution.

In a paper presented before the American Electrotherapeutic Association at the Chicago meeting (11) the following observations were made: The question has often arisen why we should not expect to obtain the same result by stimulating muscular contraction through stimulation of the neuromuscular mechanism at the motor points. Experiment, however, has disclosed the fact that such stimulation will not effect the removal of exudations. In the case reported the mildest of all the static methods was employed for inducing local tissue contraction for tissue drainage. The same or deeper effect is obtained with the static wave current, and in deeper tissues with the static sparks.

The uninterrupted static current from the influence machines is in every respect a directional current, as is the constant current—the galvanic—and, as such, delivers positive from one pole and negative from the other. It is a constant current of high voltage and small amperage, and, as such, produces, when interrupted, the same effect upon muscle cells as the low volt galvanic current plus the effect of high voltage. The experiments of Claude Bernard (12) long since demonstrated the independent contraction of muscle cells when separated from the living body by the passage of interrupted currents of galvanism to the cells. Howell (13) and all other authorities have shown the same effect of the constant current on muscle cell stimulation. With the low voltage current, however, it must be applied directly to the muscle cells and could not otherwise induce contraction beneath the resistant skin; whereas, the static current of high voltage overcomes the skin resistance, and so produces independent muscular contraction of the cell mass. This is proved because the tissues respond in an infinitely shorter time than the neuromuscular mechanism can be aroused by reflex stimulating through the motor points.

It is this independent contraction of the muscle cells which calls forth such responses when applied to infiltrated tissues that causes contraction of all cells so stimulated, and so expels the infiltration from inflamed tissues. Under observation, this may be demonstrated in all superficial cases and by the relief of pain and swelling in the more remote tissues to which the static wave current and the static sparks are applied. We can find no objection that will disprove the correctness of this point of view in the face of visual observation and subjective findings.

That other currents which produce contraction of the muscles do not effect a similar result, acting, as they do, through the neuromuscular mechanism, is due to their failure to induce independent cell contraction. These effects, therefore, cannot be accomplished with the currents of low voltage. Hence, the means of relief of a local infiltration must depend upon stimulation with the high potential constant current of very small amperage—the static current—which, acting as a local stimulus to the cells, effects the removal of infiltration wherever present in swollen tissues.

The only contraindication for such administration is its indiscriminate application over malignant tissues and to parts the seat of local infection.

The clinical results in the treatment of all manner of inflammatory conditions to which the static modalities are adapted is so remarkable that what is said of the effects is not credited by those who have not observed the results of static administrations.

There is no other effect which could explain the relief afforded the local conditions and symptoms of traumatic injuries but that given, and the indication in those cases is selfevident to all who are familiar with the subject.

A comparison with statements of authorities who employ other methods will illustrate marked contrasts with similar cases as reported.

PHYSIOLOGICAL EFFECTS OF STATIC MODALITIES

The three important physiological effects of the static modalities are as follows:

1. The effect described of removal of infiltration and exudation that engorges the tissues following an acute trauma or arising from toxic foci, including cases of rheumatism, rheumatoid arthritis and other toxic arthroses, in those of toxic origin, at the same time trouble at the focus must be removed.

2. There is no method or modality so effective in removing muscular tension always present with inflammatory conditions but never to be employed over areas infected locally or in malignant cases.

3. The effect on general metabolism derived from the active surging of the current to and fro through the body during the process of administration is remarkable.

These three effects are reasons why static electricity fills an unequaled rôle in the treatment of inflammation not associated with local infection and for the general effect upon metabolism.

The static machine and static methods have been the most neglected of physical modalities except by a few hundred well informed earnest physicians, who have learned to master the technic and employ the modalities scientifically.

As my early discoveries are largely responsible for the development of the static methods, it will be but proper to include further the numerous conditions in which these discoveries were first used with the indications and results.

CONDITIONS IN WHICH STATIC ELECTRICITY WAS FIRST USED

Neuritis.—In October, 1898, the first case of neuritis—a case of tic doloureaux—was treated by applying a metal electrode and employing the static wave current over the branches of the fifth nerve passing out through the different foramen. This severe case was of but three days' duration and was completely relieved with three treatments from a most distressing condition. Many recent cases have been promptly relieved by this and some of months' duration.

Sciatica.—In April, 1899, the first case of sciatica with the lesion at the notch was treated with the static wave current applied over the sacrosciatic notch. The

patient had not slept the two previous nights, but was completely relieved of pain and slept the first night following a twenty minute treatment over the notch with the static wave current, and was cured within ten days.

Ten similar acute cases treated in the same manner were reported at the New York meeting of the American Electrotherapeutic Association (14) in 1900, all of which had been cured with the wave current within ten days. These results were so phenomenal and unusual that they made a marked impression upon the writer at that time.

Bell's palsy and coccygodynia.—In the same communication were reported four cases of coccygodynia treated and cured by the same method, and also cases of Bell's palsy treated and cured with the static wave current. This is now with us the standard and uniformly successful method of treating Bell's palsy and tic doloureaux and all early cases of neuritis not of toxic origin, and the toxic cases also with removal of the cause.

Poliomyelitis.—The first static treatment of a case of anterior poliomyelitis (15) was given by the writer and reported in the same communication and another case was reported in full in 1903 (16). Subsequent to this, all early cases of poliomyelitis which have come under the writer's observation have been either completely restored or greatly relieved by the use of the static wave current applied at first daily and later on alternate days over the spinal cord, employing a narrow metal electrode with a spark gap of from eight to twelve inches. We now add the use of light to the spine in the treatment of these cases and exercise with the sinusoidal current in chronic cases. The use of reflected light was first established by use in the treatment of a case of a physician's daughter in Wilmington, Delaware, in 1913.

Arthritis and rheumatoid arthritis.—These conditions were first treated by the methods described, employing the static wave current and static sparks, and reported at the Washington meeting of the American Electrotherapeutic Association (17) in 1899. Since reporting these cases, upwards of forty cases have been successfully treated by the joint administration of the static modalities, radiant light and heat and mechanical vibration, with attention to diet and the alimentary conditions.

A report of two cases of Still's disease and cases of arthritis deformans successfully treated was made in 1904 (18).

Prostatitis.—The first reference to the treatment of prostatitis with the static wave current was made in 1900 (19) and in numerous contributions since that time. The relation of prostatitis to sexual neurasthenia and impotency was then considered and notably confirmed (20) in many subsequent papers and contributions. Many hundred cases treated by myself and others have confirmed the great value of this discovery which I consider one of the most important in the twenty-seven years that I have devoted to this interesting field of medical research. And now it may be stated without fear of contradiction that the surgery of prostatitis could be anticipated in many cases by the early employment of the static wave current.

Pelvic conditions.—The same is true of dysmenorrhea, uterine congestions, subinvolution and vaginismus (21) treated with the static wave current per rectum. These results have been reported variously by others.

The use of the static wave current in the treatment of these pelvic conditions in the male and female, if the static modalities were used for no other purpose, would afford sufficient grounds upon which to urge their general adoption by the profession at large, including the progressive gynecologist and genitourinary practitioner.

Visceral congestions.—In all visceral congestions not associated with the presence of local infection or malignancy, as of the liver with simple congestion or cirrhosis, the large malarial spleen, the pancreas in diabetes, the kidneys in nephritis, are found conditions upon which the author has often reported the successful use of the static current and as time passes without the introduction of better methods, he becomes the more insistent in urging the use of these modalities in all indicated conditions. Attention has been frequently called to the results in cases of large cirrhotic liver, when, if the use of alcohol is suspended, they may be reduced to the normal size; likewise, the large malarial spleen.

Exophthalmic goitre.—Exophthalmic goitre (22) was first treated with the static current by me in the clinic at the New York Postgraduate Hospital in 1899. Since that time we have treated, with marked results, upwards of twenty-five cases of this condition, employing jointly and systematically, the static wave current, x rays and mechanical vibration. Uncomplicated cases of hyperthyroidism can be relieved without exception, by any physician who is skilled in the use of the modalities mentioned. The static current plays the largest rôle in the successful treatment of hyperthyroidism.

Trauma.—In the treatment of all conditions of trauma and in all cases of noninfected inflammation and disturbed metabolism, as stated in the body of this paper, the static modalities play a rôle which no other means of any kind approaches in the results obtained. This readily demonstrated statement affords ample reason for their general adoption in therapeutics.

There have been such remarkable results in so many conditions with the static modalities in which other methods have failed that a more liberal recognition and adoption in the management of the cases referred to is earnestly sought by progressive men in the profession.

CONCLUSIONS

1. The peculiar effects of the static current are derived from the fact that it is a direct or constant current of high potential and therefore possesses the characteristic qualities of the constant current in inducing direct muscular contraction of the muscle cells.

2. The effects of the static current important in therapeutics are: a. The mechanical removal of infiltration from engorged tissues where no infection is present. b. It produces a complete relief of tense muscles when applied, thereby overcoming muscular contraction associated with the inflammatory processes. c. With the general administration of the one pole modality, it has a remarkable effect in improving local and general metabolism.

3. There is no other electrical current at present available possessing the same characteristics and capable of the same therapeutic effects as the static modalities, and, from the fact that it is so remarkable in its influence upon inflammatory conditions, it is indispensable for prompt and complete relief of those conditions.

Hydrotherapy in Mental Diseases*

ARTHUR H. RING, M.D.

Boston, Mass.

PREAMBLE

The use of water is not a fad in the treatment of disease. It has a long and honorable history—too long to discuss in a practical paper. Suffice it to say, that from the time of Æsculapius, about 4000 B.C., to the present time, whenever and wherever the healing art has been practised with enlightenment, water has played its part. Of all therapeutic agents, water is the most flexible in point of temperature variation, the most easily obtainable and the cheapest. If we could have but one remedy with which to treat the sick, water would be the agent of choice. And yet, its very simplicity, accessibility and cheapness have often led to its neglect. The tendency of the human mind to look afar off and choose the complex, while neglecting the simple near at hand, is proverbial.

RATIONAL

There are a few basic principles to be observed in the application of water to disease.

1. We must know the condition of the patient, especially his circulatory apparatus and his resistance, that is, his endurance or fatigability and his capacity to react, in other words, the state of his vegetative nervous system, in order to decide upon the severity of the treatment; for water used therapeutically is a powerful agent and like other useful remedies, such as drugs, can do much harm.

2. We must decide whether sedative, tonic or stimulating effects will be most beneficial to the condition under treatment, for, according to the procedure used, water can do each of these things admirably.

3. We must know the physiological effects of the various hydrotherapeutic procedures. Water at 96° F. is spoken of as neutral and is neither tonic nor stimulating. However, it is definitely sedative if the body is immersed in it for a fairly long time. You will recall that the average surface temperature of the normal skin is about 72° F., but varies according to the temperature and humidity of the environment, as well as the physical condition of the individual. The nearer the environmental temperature approaches the internal temperature of the body (98.6°) the more work is taken off the temperature regulating apparatus and the more relaxed the vasomotor mechanism becomes, and the blood is also more evenly distributed. The nerve terminals in the skin carry back to the vegetative nervous system and thence to the cord and brain sedative impulses which serve to relax the muscle tensions and so have a quieting influence upon the body and mind. Perhaps this is why persons residing in warm climates are more listless and relaxed. At any rate, we have in medicine no better sedative than the prolonged use of water at a neutral temperature.

If now we apply water above 98° F. or below 90° F. we begin to get stimulating or tonic effects and at very extremes of temperature, hemostatic effects, and so greater care and judgment must be exercised in their use. Hot water, i. e., over 100° F., first stimulates the vasoconstrictors for a few mo-

*Read before the First Annual Meeting of the New England Association for Physical Therapeutics, Boston, October 26 to 28, 1926.

ments, then paralyzes them, resulting in passive congestion of the skin, drawing the blood from the deeper tissues and causing blushing and an increase of slowly moving blood in the capillaries. If, on the other hand, cold water (60° to 80° F.) is applied over a short time (one half to two minutes) the same but more intense vasomotor constriction occurs with blanching of the skin but soon is followed in health by a tonic dilatation of the capillaries, active reaction in contradistinction to the passive reaction from hot water. The amount of active reaction that the patient gets from treatment is one way to measure the degree of benefit which he obtains from it.

The application of hot or cold water for its tonic effects is one of the best methods of reaching and toning up the vegetative nervous system which is really the basis of our mechanism of well or ill feeling. And since our feelings are the basis of our state of contentment, you can at once see what a potent agent water may become when intelligently used.

In all asthenic states and all nervous and mental diseases, with the exception, perhaps, of acute mania, there is a lowering of the tone of the vegetative nervous system with resultant ill feeling and disturbed bodily sensations. If the individual has a well balanced mind (i. e., a well developed and properly nourished brain) the condition resulting will be merely one of asthenic lassitude and fatigability—perhaps irritability, fatigability and depression. He will retain good insight into his condition and will cooperate in his treatment. This is the type of patient with which most of you at times deal.

On the other hand, if he has inherited, or acquired through disease, various toxins or chemical poisons, a loosely knit mind prone to misjudgments, he may readily put a significance upon these perverted feelings which is not a correct estimate or deduction. We cannot get his point of view because we have not the same bodily feelings and hence not the same outlook on life; the world—his world—is changed, and so he reads this change into his objective world, hence his delusions.

I cannot go into the psychological twists which may grow out of these misinterpretations. I desire only to emphasize the idea that they probably, for the most part, grow out of disturbances of the vegetative nervous system and its correlated endocrine regulators and that in the use of water we have a potent means of helping this state of affairs. Now, disturbance of the vegetative nervous system may be functional or organic. Dementia precox probably in its more severe forms belongs to the organic group, although as yet we have no pathological evidence beyond that of general organ inferiority. The organic diseases we may not modify; the functional ones we can often cure and the stimulating, tonic and sedative effect of water is one of the simplest and surest methods.

I do not mean to convey the idea that it should be used to the exclusion of the other remedies but rather in conjunction with them. At our sanatorium, hydrotherapy has been in use in all chronic and many acute forms of illness since 1879, when Dr. Dio Lewis put in his famous Turkish baths. We have had recourse to all that modern medicine has to offer: hygiene, drugs, sera, electrotherapy and heliotherapy but water remains our sheet anchor and no patient stays long at the sanatorium without receiving some form of hydrotherapy.

I used to wonder, when physiotherapeutic societies were first organized, why it was that I had so little to say about these methods, which I had been using so many years—even from boyhood. I know now. It was because we used none of them exclusively but always in combination. Hence, I was unable to say just what any one of them did when used alone.

One precaution I want to speak of before coming to methods. I have said we must know the condition of the patient's cardiovascular system before prescribing water treatment, and I would double the precaution in patients over fifty. If there is much arteriosclerosis, water of extreme temperatures from normal should be used with great caution. I am speaking now, not of local application, but of tubs and packs and medicated baths as the Nauheim. The reason for this is that the vessels being irregularly fatty or stiff are incapable of reacting evenly to the tonic effects and so we may get an uneven distribution of blood with congestion or anemia where it will do harm. If the coronary artery is sclerosed, and who can say at times whether it is or not, the sudden primary increase in blood pressure from complete submergence in extreme hot or cold water may prove harmful or fatal. In cerebral anemia from the tonic reaction stage, the treatment may provoke great excitement with increase of mental symptoms and exhaustion. So, while I would not say that water treatments are entirely contraindicated in these cases, I would advise proceeding with caution and giving specific directions to the person giving the treatment.

METHODS AND PROCEDURE

I will not attempt to make a complete list of hydrotherapeutic procedures but only refer to those which I have found useful in my special work.

PROLONGED NEUTRAL TUB BATH

This bath is sedative, circulatory regulator, and eliminative.

Equipment.—1, A large tub; 2, a bath thermometer; 3, a sheet of canvas to cover tub; 4, a blanket to wrap patient in (if necessary).

Technic.—Draw a tub of water at 97° F. to the overflow. Put patient in tub and immerse as completely as possible. Force fluids, keep ice compresses on the patient's head and watch his pulse. If you have the patient's cooperation, this is easy; if not, as in some cases of acute mania, it may take from two to four nurses at first. Occasionally, a patient is so disturbed and resistive that he cannot be kept in the tub; then the pack may be substituted. If the neutral tub is used for insomnia, asthenic or cardiac conditions, twenty minutes to an hour, according to the reaction and comfort of the patient, is sufficient. If you are treating a disturbed mental state the time may be lengthened to two or three hours, twice a day, or given for several hours at a time. In this latter case it is well to take the patient out occasionally and apply lanolin or other heavy grease to the whole body.

In the extreme agitation of chorea, I have found the neutral tub one of the best sedatives. Dr. Klapp, superintendent of the Allentown, Pa., State Hospital, has had installed some batteries of three large tubs

in which the patients can turn around sideways and thrash about, sit up, eat and smoke. Tubbing is an essential factor in any such hospital. A trained attendant is constantly on hand in the room.

Various control valves have been constructed to keep the water at an even temperature but none of them are absolutely dependable or even necessary. The thermometer in the hand of the attendant is safest. Restraint of the patient in the tub is only mentioned to be condemned. But a rubber or canvas sheet to cover the tub protects the patient and helps to keep the temperature even.

THE PACK

The pack is also useful as a sedative and promotes nutrition by stimulating metabolism. In some German sanatoria, it is customary to put all neurotic patients in packs at bedtime for the night. It has the added advantage (sometimes, however, a disadvantage) of acting as restraint by enforcing muscular quietude. It consists in placing the patient in a tight wet jacket. Dry packs, used as restraint, are not allowed by law in mental hospitals in this state.

Dr. Boris Sidis, from his experiments on sleep, pointed out that there were three main essentials: 1, Reduction of external stimuli to a minimum; 2, monotony of rhythm as from the heartbeat or respiration; 3, bodily immobility or muscular quietude. He found that if he bound a frog by wrapping it in a gauze bandage, it promptly went to sleep.

The wet pack fulfills most of these requirements as soon as reaction sets in, that is from ten to twenty minutes. The surface capillaries dilate, giving off some of the body heat to the wet sheets. Reflexly, the nervous system is quieted by the action of the water on the end plates of the skin and the stillness of the body and quietude, and sleep frequently ensues unless the patient is too disturbed, mentally.

Equipment.—1, A single bed stripped of bedclothes; 2, a long rubber sheet; 3, two single blankets; 4, three single sheets; 5, a pillow covered with rubber sheeting; 6, a dozen safety pins, horse blanket size; 7, a basin of water at desired temperature—usually from the cold tap. It is almost impossible to give a hot pack with sheets. They cool too quickly in handling. If a hot pack is indicated, as in kidney conditions, blankets must be used in place of sheets and handled rapidly. Cold packs are contraindicated in most kidney diseases.

Technic.—Completely cover the mattress with the rubber sheet. Over this spread two blankets. Wring out the sheets in water. Spread one fully open, over blankets. The other two should be folded once on the long way and placed across the wet sheet, so that the top one will extend from the patient's neck to the buttocks and the other lap over and extend to below the feet. (In quiet or nonmental patients, two or even one sheet may be sufficient.) The patient is now placed nude, in the middle of the sheets and the upper sheet wrapped rapidly about him, tucking it in so as to surround the arms (first on one side and then the other) and binding them to his sides. There is a knack to this. Next the feet are similarly wrapped. If patient is chilly, a gentle slapping may be applied all over. Then the under sheet is neatly wrapped and folded about the shoulders and neck and feet. Finally, the blankets are brought over and around the patient, folded neatly and pinned at foot intervals for the entire length. Place a hot water bottle to the feet and an icecap to the head and watch the pulse. The patient should warm up and become quiet. However, he should not be left alone at first, as some patients, if weak, may suffer from shock and require a hot drink or even aromatic spirits of ammonia or have to be taken out, but this is a rare occurrence. The patient may be kept in the pack for from one to three hours (which is the longest the law allows). He must be taken out, rubbed with a coarse towel, or given a warm sponge bath in cases where it would not excite the patient, then put to bed if quiet enough. Of course in cases of acute mania the patients often want to be up and doing and will not rest.

HOT SPINAL FOMENTATIONS

This is another procedure of great use as a sedative in mild cases of nervousness and at night for insomnia.

Equipment.—1. Some coarse kitchen toweling made up like a roller towel about two feet long with two sawed off broom handles inserted in the ends. 2. A piece of old flannel blanket about eighteen inches wide and as long as the patient's spine, folded to six inches in width. 3. One small blanket folded to cover the back. Bath towels may be used in place of both of these but do not hold the heat as well. 4. Some boiling water.

Technic.—The folded blanket or towel six inches by twenty-four inches or so is immersed in the boiling water and placed in the wringer, the two ends being twisted until it is fairly dry and steaming. In this condition it is carried to the bedside and, with the patient lying comfortably on his face, is taken out of the wringer and laid, gently at first, along the patient's spine from neck to sacrum and quickly covered with the dry blanket or towel. The hot towel is changed every five or ten minutes when it gets cool for three to six times. The back is then dried and the patient left comfortable for sleep. No procedure except, perhaps, the deep therapy lamp, will help backaches so rapidly and the hot spinal compress is certainly preferable in insomnia. In acute colitis it helps wonderfully.

The tonic and stimulating treatments all have for their object the creating of an active hyperemia, rather than the passive one produced by the foregoing methods. Three factors are involved, 1, the time or duration of application; 2, the temperature, and 3, the pressure. While many of these treatments may be given at home most of them require special apparatus in order to obtain the best results.

THE SHOWER OR NEEDLE BATH

The mildest stimulating treatment is the simple rain or body needle douch. In the home the pitcher pour on the spine may be used while the patient sits in the tub. The rain shower is turned on at a comfortable temperature and gradually over a minute or two is run as cold as the patient can stand it. He is then briskly rubbed down with a bath towel.

The shower may be preceded by a few minutes in the electric light cabinet to warm him up and various degrees of heat and force of shower may be used according to the endurance of the patient.

The stronger patient may come from under the

shower and be vigorously rubbed with ordinary table salt and then return to the shower when he rubs the salt off as the water runs cold. He is then dried. This is a very stimulating treatment and leaves a great sense of well being. It is called the salt glow because it leaves a very active hyperemia. As a general tonic it has no equal.

SCOTCH DOUCHE

This is for the more robust cases and is especially useful for alcoholics. The patient is placed in the electric light cabinet, his feet in a foot tub of warm water and a towel wrung out in ice water about his head. Here he remains until he perspires profusely (ten to twenty minutes). He then goes under the warm shower to rinse off. The hot (105°) and the cold (65°) hose is next turned on and played upon him alternately beginning at the feet and slowly working over the entire body. Then twenty to thirty pounds of pressure (about street pressure) is used at from a distance of from twelve to fifteen feet for two to four minutes. This massages the tissues and produces an active and deep hyperemia which greatly relaxes restlessness and produces a comfortable glow and quickens metabolism.

I believe that there is no procedure in medicine which so well reestablishes functions without any unpleasant or harmful reaction—excepting, of course, exercise and this should be added, through the day, in the form of walking, medicine ball, etc.

I might describe many other methods of applying water in disease but these are the ones we have found especially useful.

When we are dealing with sluggish or otherwise disturbed functions and local congestions, as we do in practically all nervous and mental conditions, for the trouble is often as much or more in the body than in the mind, and in toxic states, especially in the bowels, there is no single agent that alone or in combination will give such satisfying results as water properly used.

Some Aspects of the Biological Action of Light

FRANZ NAGELSCHMIDT, M.D.
Berlin

The great confusion present in the literature of light treatment is due chiefly to two factors: one is the insufficient consideration of the physical composition of the radiations emitted by the usual lamps as well as the difficulty of the measuring methods; the other is caused by the most complicated mode of reaction of the biological object, especially of man, to light.

If we speak of light simply as of the sun or the carbon arc lamp, this designation is very inexact. For these sources of light contain besides visible light, other invisible, infrared heat radiations and invisible ultraviolet rays of different wave lengths. And if we speak of ultraviolet light, we are using ultraviolet rays of widely varying biological efficiency, beside visible light and some heat radiation.

PSYCHIC EFFECT OF LIGHT

Many biological reactions are confined to very narrow limitations of wave lengths and even spectral areas situated close together have partially opposite actions. Let us only consider the small spectral parts of visible light comprising one single octave, i. e., the wave lengths from 7600 to about 36 Angstrom units. We here find very different actions. If we observe the indirect psychic effect through the eye, we notice that the different colors act evidently quite differently. It is not a coincidence that in churches and mausoleums the blue and violet tones are prevalent while in ballrooms and places devoted to social pleasure the reds and yellows prevail. The latter have a vivifying and exciting psychological action, while the violet end of the spectrum acts in a soothing and sedative manner. Therefore the bedrooms in hospitals, especially in asylums for the insane, where turbulent patients are kept, have, or should have, violet lighting at night.

PHOTOTROPISMS

Many examples could be alluded to in the territory of zoology and botany which are known to us as *phototropisms*. In physics blue and violet rays excite for instance a bright phosphorescence on a screen of zinc sulphite, which persists in the dark for hours. If you transport such a brightly lighted screen to a dark room, cover one half of it by a metal plate and irradiate the other half by a red lamp, the phosphorescence is instantaneously extinguished while the covered half still shines brightly. This effect is more definite and quicker if one excites by ultraviolet and extinguishes by infrared. But this experiment proves that radiations which in the spectrum are only distant three hundred millimicrons can have even opposite actions, which annul each other. Three thousand years ago the Chinese knew and practised the treatment of smallpox in the dark room and Finsen has reintroduced this treatment as negative phototherapy. But it seems to me uncertain if we have to deal here really with a negative light therapy, or if the action of the red rays is not too to be considered as a positive one, only as one which is opposite in this case to that of the blue radiation with shorter waves. (See later neon light.)

So, if we observe on so narrow a space, differences of actions or even opposite effects, it is not astonishing that in farther distant areas still bigger differences occur. If we irradiate simultaneously with differently acting radiations, it is clear that their action will be a very complex one and represents a result of the partly opposite, partly equal, actions.

EFFECT OF TEMPERATURE ON ENERGY DISTRIBUTION IN SPECTRUM

Further, the distribution of energy in the spectrum is greatly dependent upon the temperature. If, for

instance, a carbon arc lamp is burning with a certain amount of current, the carbon gases in the light arc show a temperature to which certain intensities of radiations in the spectrum correspond. If we raise the intensity of the current, the energy distribution in the spectrum changes and the maximum proceeds more against the short wave part; opposite if the current intensity diminishes. Such variations occur almost constantly because the line tension varies, the carbons burn unequally or are not equally composed, air currents are disturbing, etc. In consequence the relative intensity of radiation of the single spectral territories will change, too, and the total action as sum or difference of the single actions will be a different one.

Conditions are similar in the sunlight. While practically the sun is to be considered as a constant source of radiation, yet the composition of its radiations striking the surface of the earth changes depending on the position of the sun, i. e., the time of day or the season, on account of the different direction of the rays, of atmospherical influences, dust and water content, clouds, air currents, etc. The artificial alpine sun, too, is much dependent on the line tension and on its own heating. In the first ten minutes of its starting, variations of fifty per cent. in the intensity and more may occur and mercury vapor lamps of different factories show quite different intensities over the ultraviolet spectrum concerning the energy distribution.

The same is true of other lamps and so it is clear that all investigations and practical experiences with a combination of different radiations at the same time can only give an empirical and by no means exact knowledge of the action of light. As shown by the above we have to deal with different actions of the different parts of the spectrum.

METHODS OF MEASURING ACTION OF LIGHT

The second difficulty lies in the methods of measuring. We are in possession of only one way to state the exact value of a light source, that is, the spectral decomposition of the emitted rays for qualitative characterization of the radiation source, and the quantitative measurements of the intensities in the different spectroscopically separated spectral areas by very sensitive galvanometers or thermopiles. Both examinations are very difficult, take a long time, demand a thorough training in physics and cannot be employed in daily medical practice.

Now let us suppose that this question may be solved or that the factories deliver us monochromatic lamps with a well defined output of radiant energy which in fact is not yet the case. Even then new difficulties would arise. If you apply radiation to the surface of the body, it is practically impossible to make this application so that all rays hit the body at the same angle; from the angle depends to a very high degree the reflection and from the reflection is dependent how much of the radiation is lost for therapeutical application. You can easily prove that even for ultraviolet rays the reflection plays an important rôle; if you take an ultraviolet lamp closed by a dark filter which permits the passage of ultraviolet rays only and not of visible light, and then expose a fluorescing screen not to the direct radiation of the lamp but to reflected rays, for instance from your hand, you see that a very strong fluorescence takes place. This reflection is further dependent on the state of the skin, on the position of the body which is to be treated, the sweat production, the pigmentation, or the presence of hyperemia or anemia. So even the exact control of the energy output of the lamp will never give an exact estimate of the dose actually applied, as the above described variations vary further for the different spectral areas.

These difficulties seem very hard to eliminate. Still greater difficulties arise at the moment the light enters the body. We believe that radiations of light are only active as far as they enter the tissue, even at a very superficial layer, and are absorbed. But we do not know exactly which part of the entering rays is absorbed, at the different depths of the tissue, as an unknown part is dispersed by passing through the tissues, another unknown part is transformed into heat, another one into chemical energy, another into other light radiations (for instance fluorescence), another one is stored by the pigment nuclei and some may be stored in some other still unknown way. The specific effect, however, depends on the absorption in a special tissue.

DIFFICULTY OF ESTABLISHING LIGHT THERAPY ON AN EXACT SCIENTIFIC BASIS

It seems hopeless for the moment, considering all these very complex relations, to bring light therapy out of the present empirical stage, to an exact scientific status. But much could be done if the factories would at least provide us with light sources delivering monochromatic light, a task which I gave to some of them many years ago without practical results. The only lamps which partially approach this demand are the dark infrared lamps, the neon lamp, and the mercury quartz lamp. But even here the spectral spaces are not yet narrow enough. Some examples may prove this.

Visible light is differently absorbed by normal serum and pathological serum and the same is true for ultraviolet rays. Normal serum, for instance, has an absorption maximum at 2800 A, a minimum at 2530 A, and later to shorter waves a very great increase of absorption. For serum, containing gall stain, the maximum lies between 2500 to 2900 A, but if you mix artificially serum and gall stain, so it absorbs differently, that shows that there may be perhaps still some other absorbing substances in the icterous serum.

Another example for visible light is in the growth of mice tumors. The wave lengths of 7200, 6500, 5500, and 5000 A increase the growing of sarcoma; 6700, 6000, 5250, 4700 A decrease sarcoma. But 6500 A, which increases sarcoma, decreases carcinoma. So we observe that very narrow spectral areas in the visible part of the spectrum have a different effect and the difference is even present for the same wave lengths for an epithelial tumor or one of connecting tissue. It may be that absorption bands of the pigment play here an active rôle.

If you expose a series of mice with tendency to spontaneous tumors to sunlight, the percentage of mice tumors will increase; in the dark it will decrease.

For bacteriological examinations the strongest bactericide is shown by the wave length 3000 A. This action belongs to a very narrow zone while other

spectral parts have an action which is three to four thousand times less.

PRODUCTION OF ERYTHEMA

If we expose the skin of the arm to sunlight we shall have a light erythema, if the dose is sufficient, but a place protected by a piece of glass will remain free of erythema. This experiment has been made by Finsen. As the sun contains ultraviolet rays at the earth level only about down to three thousand Angstrom units and through glacss all visible light and ultraviolet rays pass, down to three thousand two hundred Angstrom units, the erythema producing area must be situated between 3000 and 3200 A, for sunlight. Some shorter ultraviolet rays have this effect, too; but experiments I have made with a new mercury quartz lamp producing ultraviolet rays down to 1900 A have proved that the shorter ultraviolet rays have no considerable effect on the production of erythema.

So we see once more that even lamps producing chiefly ultraviolet rays must be of very different action depending on which region of ultraviolet the maximum output of energy is present. One lamp may even produce the active ultraviolet rays, but in a not sufficient quantity; yet at the spectroscopical examination the qualitative presence of the desired rays may be shown and only the quantitative examination would prove whether the amount of this radiation is sufficient or not.

THE NEON LAMP

The neon lamp corresponds to the demand of monochromatic lamp best of all so far. It emits only red and yellow rays without infrared. This lamp has a very marked, positive action on pain and besides has strong antileucotactic and antiphlogistic actions. It is necessary to apply the neon lamp in a dark or nearly dark room, because, as we have seen, the white light contains rays acting in the opposite direction to the red ones.

Altogether we may conclude that we are not yet in possession of radiating apparatus producing one narrow space of spectrum just needed for a certain purpose and that our measuring methods are still far from perfect. On the other hand, our clinical and experimental researches have provided us with a great number of single facts concerning light biology, so that we are able in practical medicine to secure a good many therapeutical results with sufficient certainty.

RICKETS

We know that we can cure rickets, the spontaneous rickets in children as well as the experimental in rats, with ultraviolet light. This action is produced only by the space between 2900 and 3200 A. The optimum is situated at 2970 A. Radiations of rather different —greater or smaller—wave lengths are inefficient. Further it has been proved that black rats require much larger light doses to show the antirachitic effect than albino rats. And so in men, too, we shall have to measure the light doses, depending on the pigmentation of the skin. On the other hand, we know that we can heal natural or experimental rickets by administering vitamines, and so we may suppose that the curative action of sunlight in animals and men is analogous, i. e., it produces vitamines.

We can just as well influence the blood level of calcium and phosphate and control troubles in the production of bone substance in children. We know that cholesterol is influenced in the skin, the blood, and in internal organs, for example, the liver; many other actions are produced, for instance, the relation of albumin to globulin in the serum and the degree of sugar tolerance are influenced.

BIOLOGICAL ACTION OF LIGHT BATH

If we consider the biological action of a light bath, this action cannot be explained in a simple way. Sonne has shown that on the inner side of the forearm one can endure on a spot of about one inch in diameter 3.11 calories per sq. cm. and per min. of visible rays; 1.79 calories of inner infrared rays, and 1.33 calories of outer infrared rays.

If you apply visible light on the same place with the greatest tolerable intensity, the skin temperature rises for visible light to 43.8° C., for infrared to 45.5°. But after fifteen seconds it changes; then there is a temperature of the skin one degree higher for visible light than for infrared. It seems that the deeper situated layers are more intensely heated by visible light.

If you control the temperature at different layers during the application of infrared radiations, you find that to a superficial temperature of 45.5° C. corresponds in one cm. depth a normal temperature of 37° C. If by visible light irradiation the surface reaches a temperature of 43.8° C., in 0.5 depth a maximum of 47.5° C. has been proved, while infrared shows in the same depth only 41.7° C., i. e., 5.8° less. It proves that we are able to heat the blood in and under the skin by means of light rays to a temperature several degrees higher than we can with the maximum tolerable intensity of infrared radiations.

If we consider that all these changes and many others, reference to which here would lead too far, are produced by an energy which is absorbed, at least partially, in the most superficial layers of the skin and do not even reach the superficial capillary layer, we can only explain this action by supposing a direct or indirect irritation of the sympathetic nervous system and by so changing the balance of the sympathetic and parasympathetic nervous systems as to influence the internal secretions. We know that these mechanisms are very complicated, even in response to much simpler and more definite irritations occurring in experimental investigations, and much depends not only on the individual but on the momentary disposition of the individual in regard to the response of the different functions to one and the same irritation.

CONCLUSION

In conclusion I would state that without well defined monochromatic light apparatus and exactly worked out measuring methods no further scientific investigation can be accepted as reliable, and it seems that we shall have to repeat most of the experimental investigations done in light up to the present time by controlling as many of the above described factors as possible in order to secure reliable and practicable results. Then only will light therapy become a real science.

The Static Modalities in Gynecology*

MARY L. H. ARNOLD SNOW, M.D.
New York

The status of static electricity in gynecology as an electrotherapeutic agent of value is dependent on results, be they palliative or curative, being limited in the prognosis by the cause and conditions presented.

The causes of gynecological derangements are functional or organic, varying with age. In youth the most common condition is due to interference with the menstrual function which may be a reflex state due to disturbed nutrition, rarely developmental, or else inflammation, primary or secondary, as caused by constipation, disease, sexual habits or trauma. Sometimes functional disease under favorable conditions becomes organic when endometritis or later even ovaritis may occur. In older patients trauma, disease, infection, subinvolution and even nutritional disturbances are causative factors. Considered as a whole, the outstanding representative element in results of causes is stasis with active or passive congestion.

The problems presented are representative of the removal of inflammation with its accompanying symptoms, chief of which is local stasis, evidenced by tenderness and swelling, and in cases involving the uterus, with irregularities of menstruation with misplacements and their consequent conditions.

The aftereffects of inflammation are infiltration and increased tension with or without pain. There is an altered integrity of the part with changed or limited functional activity often associated with reflex neuroses.

Recognizing the premises of the problem presented, it may be readily appreciated that for palliation or relief, the remedial measures must primarily affect the removal of the local stasis in order to relieve the active or passive congestion. By mechanical, chemical and thermal measures it is possible to restore local metabolism, and to correct reflex manifestations and nutritional defects and thus further the elimination of wastes, and promote reconstructive processes. Treatment must determine the site of local pain, remove infiltration and lessen or overcome muscular spasm or tension. As in all departments of medicine, the causative factor must be controlled or corrected.

The static modalities are preeminently most efficient means when used alone, or together with other physical measures for the treatment of gynecological conditions. The supplementary modalities include the sinusoidal or wave generator currents for mechanical exercise; the high frequency currents for their chemical and thermal effects, restorative in action with diathermy or destructive by desiccation, fulguration or carbonization; the constant current for its destructive action; mechanical vibration for its massage effects, or nerve inhibition or stimulation; ultraviolet rays for their antiseptic effect and stimulating activity; as well as the carbon arc lamps promoting metabolism, and the x rays and radium inhibitive or destructive in character.

*Read at the First Annual Meeting of the New England Association for Physical Therapeutics at the Copley Plaza Hotel, Boston, Mass., on Wednesday, October 27, 1926.

STATIC MODALITIES EMPLOYED IN GYNECOLOGY

The static modalities employed in gynecology are, 1, the static wave current; 2, static sparks; 3, static brush discharge; and 4, the static induced current.

The static wave current is devoid of disagreeable sensation and absolutely free from injurious effects in noninfectious inflammatory conditions. The effects are mechanical, producing alternate contraction and release of muscular and elastic tissues with a force whose strength can be regulated to conditions. "Locally (1) conditions of stasis and local stagnation are overcome by the action of the current with restoration of circulation and local tone of the arterioles with resumption of normal conditions with stasis removed. These effects are not merely superficial but varied in their depth of penetration in proportion to the amplitude of the current which is varied by increasing or slowing the speed of the machine and by lengthening or shortening the gap." Independent contraction (2) of the muscle cells is produced in this manner, relieving stasis locally, restoring circulation and removing muscular tension. Amelioration of or freedom from pain follows. "Heat production (3) due to a greater degree of tissue oxidation coincident to general increase of metabolism is one of the remarkable effects of this modality." The effects on general metabolism are striking. It aids in eliminating tissue wastes (4), overcomes muscular tension and promotes the functional activity of a part as is seen in the results of the treatment of dysmenorrhea. With this change is a marked amelioration of the nervous symptoms with a feeling of well being on the part of the patient.

The glass vacuum tube, in place of the metal used for the wave current, "relieves superficial local congestion and induration (5)" and also has an "analgesic action (6)."

Static sparks when given with or without a spark director relieve muscular tension and favorably affect local infiltration with stimulation of the circulation.

The static brush discharge is rubefacient and depleting in action, draining the tissues, thus relieving local stasis and tension, reducing swelling and rapidly removing ecchymoses.

The static induced current—a two pole current—produces the same local mechanical effects at the two sites covered by metal electrodes as does the wave current at a single site.

The gynecological conditions amenable to treatment are amenorrhea, cervicitis, endometritis and cervical erosions, dysmenorrhea, uterine retroversions not complicated with adhesions, vaginismus, ptosis, hemorrhoids, rectal fissures, spasmodic stricture of the anus, subinvolution, renal incontinence and coccygodynia.

AMENORRHEA

Amenorrhea with total absence or scanty flow, menstruation having been present, when not due to surgical operation, paralysis, malignant disease, ob-

structive lesions or cysts, is relieved by the use of radiant light and heat anteriorly and posteriorly over the pelvis for one half hour daily followed by the static wave current applied with a proper electrode per rectum for twenty minutes daily, the rectal electrode being attached to the positive pole of the static machine, the negative side being grounded with a spark discharging at the spark gap three to three and a half inches in length or less, regulated according to the patient's tolerance. Diathermy may be used for three quarters of an hour or one hour in place of or in combination with the radiant light and heat treatment with a view to increasing the local circulation in the pelvic organs. Treatment should be at least on alternate days for one month. The placing of the electrodes is important and is best accomplished with the patient lying on her side with knees flexed; the electrode is then inserted through the anus and carried up so as to lie pressing against the uterus. The static treatment as given per rectum is a most desirable form of treatment for such cases. If necessary to have treatment a second month, it may be given three times a week until ten days before menstruation when treatments should be given daily.

CERVICITIS AND ENDOMETRITIS

Cervicitis and endometritis are treated with the static wave current, or diathermy per rectum with the metal electrode. With married women treatment is also given per vaginam, a glass vacuum tube being placed against the cervix when the static current is used; or a metal electrode is employed when diathermy is selected. The selection of the modality depends on the inflammatory condition presented, whether noninfectious or infectious. Associated cervical erosions caused by a varicose ulcer are corrected by overcoming the congested condition present as in a uterus that is swollen, infiltrated and indurated so the tissue is impoverished. Both the metal electrode per rectum to affect the muscular tissue of the body of the uterus, and the glass vacuum vaginal electrode to affect the cervix in connection with the static are used, each for twenty minutes. An associated menorrhagia, or metrorrhagia, should be treated by the x ray.

VAGINITIS

For gonorrheal vaginitis and endometritis, diathermy may be used with adequate heat to destroy the gonococci or the static vacuum tube current which may give favorable results.

DYSMENORRHEA

Dysmenorrhea, when associated with retroversion of the uterus, is successfully treated in all cases not due to an incurable, irremovable, strictly surgical cause or an adherent appendix. The treatment is given with the static wave current per rectum with a metal rectal electrode applied for twenty minutes daily for one month between periods and on alternate days for a period of eighteen days the next month, after which daily treatments should be given for ten days or until the period recurs. If dysmenorrhea is associated with a scanty flow, radiant light and heat over the abdomen and back for twenty minutes preceding the static treatment or diathermy may also be employed. If dysmenorrhea is associated with a profuse and prolonged flow, the x ray should be used three times weekly for a short period of time, employing a five inch spark resistance with two milliamperes of current for fifteen minutes or less as conditions indicate, with two mm. of aluminum as filters at fourteen inches distance each time making two exposures, one anteriorly and one posteriorly.

This method of treating dysmenorrhea was discovered in the treatment of a case of constipation twenty-two years ago. The patient had suffered from dysmenorrhea for twelve years. After one month's treatment with the static wave current per rectum with a metal electrode which was used for the treatment of the constipation, the patient was menstruating without pain. Since then, the results in these cases have been uniform.

VAGINISMUS

Vaginismus, whether true, or pseudo or secondary, is treated with the vacuum tube wave current, the electrode being attached by a connecting cord to the positive side of the static machine, the negative side being grounded, the spark gap not exceeding three inches, the length of the gap being limited on account of an otherwise possible puncture of the glass. The duration of treatment is twenty minutes. Sometimes in severe cases even the smallest handle of an electrode must first be used, the electrodes being followed by increasing sizes as improvement progresses. The causes of secondary vaginismus (7) as early hemorrhoids, rectal fissures, vaginitis, urethral caruncles, cervicitis, cystitis, displacements of the uterus or ovaries, must be relieved together with the treatment of the vaginismus. This method of treatment is easily given by the operator, uncomplainingly accepted by the patient and the results, as a rule, are very successful.

Case I.—The patient, Mrs. X., had suffered from vaginismus for ten years. Treatment was given as above described. There was complete relief within a month.

The average case is relieved with comparatively few treatments. This method has proven successful in the hands of Dr. Barton Cooke Hirst as noted in his paper of recent date.

ENTEROPTOSIS

Intestinal or gastric ptosis may be improved by the static wave current applied to the abdomen by means of a metal electrode. The length of treatment is twenty minutes and the frequency of application is daily at first, the intervals between treatments lengthening with improvement. The effect is to tone up the abdominal muscles and thereby increase abdominal tonicity and the patient's well being.

HEMORRHOIDS

Hemorrhoids, if sporadic, may be relieved by the wave current employing the glass vacuum hemorrhoidal electrode followed by the wave current over the liver. Otherwise the desiccation method of Dr. William L. Clark is a very practical and successful method.

RECTAL FISSURES

Rectal fissures are treated with the vacuum tube wave current attached to the negative side of the static machine by a connecting cord, the positive side

being grounded. The length of the spark gap is three inches. The duration of the treatment is twenty minutes. The negative side of the static is selected owing to its greater chemical action.

STRICTURE

Spasmodic stricture of the anus or sigmoid is overcome by the use of the static wave current per rectum, employing a rectal metal electrode or a special one for the sigmoid. Otherwise mechanical vibration may be used, employing the conical vibratode well lubricated and applied with moderate speed, and full stroke, of such a vibrator as the Victor, for five minutes daily.

UTERINE SUBINVOLUTION

Subinvolution is successfully treated with the static wave current applied per rectum as in the treatment of dysmenorrhea, using the rectal metal electrode attached to the positive pole, the negative being grounded, the spark gap being three inches, and the time twenty minutes, to be followed by the glass vacuum tube per vagina with the wave current for fifteen or twenty minutes daily. The patient lies on her side, assuming the Sim's position for the rectal treatment, and on her back with limbs flexed for the vaginal treatment. For subinvolution with menorrhagia the x ray is used to arrest the hemorrhage.

Case II.—The patient, Mrs. S., gave a history of ectopic pregnancy after operation, followed by a long period of illness. She was melancholic and presented the picture of a nervous and physical wreck. The diagnosis was uterine subinvolution with associated constipation. The treatment was radiant light and heat for its tonic effect; mechanical vibration for the correction of the reversed postural relationship of the patient's blood pressure; static wave current per rectum with the metal rectal electrode, and per vaginam with the vaginal glass vacuum tube. After eight weeks' treatment the relief of the pelvic condition was complete and her melancholy and nervous symptoms disappeared. Three years later her brother, a physician who referred her to us, reported complete recovery and continued good health.

Case III.—The patient, Mrs. M., suffered from a congested uterus which was five inches in length, and the cervix was two inches in diameter. Her only child was seven years old. After one month's treatment she became pregnant, a miscarriage at six months was followed by profuse hemorrhages which were arrested by the use of the x ray and the static wave current per rectum. The hemorrhages were arrested after two treatments. She became pregnant and has since borne two children. Now twenty years since, she has not had further pelvic disturbances. The same patient was treated for and cured of exophthalmic goitre.

INCONTINENCE OF URINE

Sudden incontinence in women when due to cold is relieved by the static wave current applied by means of a metal electrode placed over the bladder. The length of treatment is twenty minutes. Usually three or four treatments will suffice. Dr. Sinclair Tousey (8) in cases where one symptom is a congested vesical trigone, uses the static induced current applied rhythmically by means of a metal electrode in the vagina as close as possible to the vesical trigone and a large metal electrode over the hypogastrium. Treatments are for fifteen minutes, two or three times a week.

COCCYGODYNIA

Coccygodynia, usually the result of a fall, is treated by having the patient sit on a metal electrode which is divided and bent at right angles so that its upper half covers the coccyx posteriorly, and the sacrum. The metal electrode is about ten inches long and eight inches wide, being cut across in the middle from each side for a distance of about three inches. It is in the line of this cut that the electrode is bent. Associated bruises are relieved by the static brush discharge. It should be applied sufficiently long to get a rubefacient effect. The local muscular tension is still further relieved by static sparks applied by means of a spark director. Usually less than six treatments in recent cases give complete relief. Occasionally the static wave current with a metal rectal electrode applied internally is an effective aid.

BACKACHE

Pelvic backache often follows childbirth or a surgical operation whereby a sacroiliac strain or possibly a subluxation occurs. Radiant light and heat followed by the static wave current, together with or without manipulation, and later sparks are indicated. Lack of time forbids a lengthy consideration.

SUMMARY

1. The static current favorably affects stasis when the inflammation is noninfectious in character.

2. Stasis with active or passive congestion is the representative factor of most pelvic conditions.

3. The static current for gynecological application is mainly the static wave current with a metal or a glass vacuum electrode, although static sparks, the static brush discharge and the static induced current are also of value to meet conditions as presented.

4. Electrotherapy like surgery has a selective field in the realm of gynecology. It does not infringe, nor does it do the impossible. Only by a careful consideration of conditions presented and a selective discrimination of the modality indicated to meet requirements will palliative or curative results follow.

Some Types of Neuritic Reflex Pains Not Generally Recognized*

Treatment by Physical Measures

WILLIAM MARTIN, M.D.
Atlantic City, N. J.

We have learned long ago that pain from organic conditions may be referred to distant points and naturally look for its source with some feeling of security in finding it, but the type of pains under discussion here are not so generally recognized, since they occur at times where one would least expect them to locate. These neuritic pains naturally follow the nerve distribution, and it is for this reason that they are at times problems to be solved.

It would be impossible to deal with all such conditions in a necessarily short paper, so it will be my intention to take up only a few main types, and treat even these briefly, touching the high points for sake of brevity.

Of those that may be considered to be of great importance from the viewpoint of intensity and seeming gravity, we have pain as a result of a neuritic involvement of the cervical and brachial plexes. This involvement may be of both or only one, but since they are frequently associated, they will be considered together. If a brief résumé of the anatomy of these plexes will be permissible, we will gather a better understanding of this.

ANATOMY OF BRACHIAL AND CERVICAL NERVES

The brachial plexus is made up by the union of the four lower cervical and first dorsal nerves. The distribution of the upper dorsals is to the tissues over the heart and body walls. Parts of the first and second dorsals supply the upper inner surface of the arm and ulnar border of the forearm. The second, third, and fourth cervical nerves supply the skin of the occiput, neck and shoulders. The fourth cervical also descends to the front of the chest as low as the third rib, where it overlaps with the second dorsal. The second and third dorsals go to the inner half of the upper arm, axilla and chest, meeting and overlapping with the fourth cervical. The fourth and fifth dorsals go to the chest and the fifth goes as low as the upper part of the epigastrium. One branch of the brachial plexus, the communicating, completes the phrenic nerve which arises by three heads from the third, fourth and fifth cervical nerves, which in its distribution sends filaments to the pericardium and communicates with the plexus of the sympathetic in the abdomen.

PATHOLOGY OF NEURITIS

In addition to this brief statement of the anatomy, some mention of the types of neuritis and their pathology will be helpful. We recognize neuritis as an inflammation due to several possible causes, the chief being a local or systemic infection and trauma of various kinds. A focal infection is perhaps the chief factor in the average case and while this may be slow in its progress, it eventually will bring about a typical attack of neuritis. There are cases, however, that have all the earmarks of a neuritis from the viewpoint of pain, yet are not true cases. These are what we term perineuritis, wherein the inflammation is limited to the perineural tissues, pressure from the serous inflammatory exudate within the nerve sheath producing the exquisite pain. If the exudate is absorbed early without becoming organized, the attack will be short lived, but it becomes the site for future trouble, if the focus is not eliminated.

INTERSTITIAL AND PARENCHYMATOUS NEURITIS

The true neuritis is of two main types, interstitial and parenchymatous, the former involving the connective tissue of the nerve trunk and the latter the medullary substance and the axis cylinders. The interstitial is the more common of the two. Each may have the usual acute, subacute and chronic stages. These are more frequently the result of a systemic infection or disease, such as diabetes, malaria, alcoholism and lead poisoning.

With these facts in mind we can readily see how the pain of a brachial neuritis may affect the cervical nerves as well, and the pain reference may be to distal points of either or both distributions.

There is one type involving the occiput that has for one of its features a dull occipital headache. The point of pain is about the size of a silver quarter and is located at one side of the cervical spine, and is very sensitive to pressure, in fact, direct finger pressure will send a pain directly through the head, apparently. There may be with this a wry neck, painful with any motion of the head, and the soreness extending along the muscle course. If one palpates carefully he will find an area of infiltration that suggests lymphstasis, and this may extend throughout the whole side of the neck. The wry neck is not always present, and when it is, the involvement is usually more severe and of longer standing.

Unless one thinks of the nerve distribution here the tendency will be to consider it to be a myositis and treat it accordingly, using the drugs generally given for headache. If, however, the other thought is in mind, the static wave current will be used to test out the trouble and this will readily be found if the current is applied to the brachial plexus. My experience is that if applied to the area near the shoulder cap, the painful response will be greatest, with the other areas following in a lesser way. For the occipital pain, testing with a metal electrode is not so satisfactory, so I use the nonvacuum surface tube, the smaller the better, and test that way. Treatment is with the same current applied in the usual manner to the surface of the plexus, and the tube to the occiput, attached to the positive pole, just as is the metal electrode. After a few treatments the headache tendency will disappear. In many instances one treatment will take care of the occipital part and the headache will entirely disappear.

Another unsuspected type of referred pain from this plexus is that affecting the index finger of the

*Read by invitation before the New England Association of Physical Therapeutics, October 27, 1926.

mechanic. The middle finger may be likewise affected but usually the index is the principal one. This is more likely to occur in winter time when he is using cold tools, and then the pain is intense. One other feature of these cases is the anesthesia of the finger, a sort of paradox. When grasping a cold wrench, the patient will not feel it in his grasp, yet when attempting to use it the pain will come on with more or less intensity, and he has to give up the attempt. Inspection will show a blanching of the finger very much like a chilblain, yet in my cases there has been no such involvement. This I have learned from close questioning in each case. Local treatment of the finger will bring no satisfactory response, and in those cases that have been referred to me this has been tried out faithfully but in vain.

Testing the brachial plexus with the static wave current will demonstrate where its origin is and the treatment must be conducted in the same manner as for a brachial neuritis, except that in some cases we will have to follow down the nerve course instead of limiting the treatment to the shoulder area alone. Indirect sparks are always advisable, as the finger can in that way receive its full share of the current. The milder type of cases of this kind will need no other treatment than that directed to the brachial plexus.

The third type of involvement of this plexus is that in which the precordium is affected, simulating angina pectoris. This offers a diagnostic difficulty and suggests a grave involvement, therefore being the one type of referred pain that must receive particular attention. This has been the subject of former papers, with which fact many of you are cognizant, and I feel its importance should not be underestimated.

Since a full consideration of this phase of reflex pains may be had from my former papers, I will give this condition but brief mention here, notwithstanding its great importance.

Referring back to the nerve distribution we can see how a pain from a brachial neuritis may be referred to the area supplied by its branches, the cardiac area and the arm particularly, simulating a true angina. If we have in addition a myocardial insufficiency, the similarity becomes greater, and many a patient has had this diagnosis and its accompanying grave prognosis given him, all of which makes for ill health and despondency and all that accompanies such a prognosis.

When a patient consults the average physician with this type of pain with its symptoms so significant, a diagnosis is usually made upon the existence of the pain plus the cardiovascular findings, without a careful inquiry into other facts that may accompany these. There are certain features of a true angina that are absent in these cases, and this can only be elicited by a close cross examination, losing sight for the time being of the greater signs. The lack of hypertension, the pain not always being distinctive or always the same in its distribution, and the lack of the feeling of impending dissolution, etc., will help to eliminate the true type. Then with the suspicion of a neuritic involvement in mind, when the static wave current test is made, we have with the painful response a fair evidence of the neuritic condition. This may not always eliminate a true angina, for this may have an accompanying neuritis, thus being complicated, and it will be only after a sufficiently large number of treatments that a diagnosis can be made with any degree of certainty. If it is a pure neuritis, treatments for this condition will bring the response, but if a true angina, this will not be the case. In such cases where there is myocardial insufficiency, we must add the heart diathermy for muscle nutrition, and happily these cases have shown excellent results in my experience. Usually after a few treatments by the use of the wave current and sparks the pain has largely decreased and the patient's spirits have risen in proportion, so that it is surprising how quickly the case is turned from despondency into hopefulness.

Now leaving this fertile area we go to the sciatic reflexes, the main ones being painful but not of a grave nature. Backache, which is frequently the result of a sciatic neuritis, will not be considered here since it offers very little difficulty in diagnosis.

The one often unsuspected condition is painful knee joint. This is generally looked upon as arthritic in character and even in some cases without demonstrable pathology, this diagnosis has been made and insisted upon by competent men. This fact may be best illustrated by the citation of a case of the type under discussion.

A gentleman from your vicinity suffered for five years from what was diagnosed in turn by twenty good internists and surgeons to be a double arthritis, the diagnosis being made from the objective symptoms and in spite of negative x ray findings. He was under observation from three to four weeks in one of your city hospitals, having all kinds of examinations and tests made, the only thing found being one abscessed tooth which was extracted promptly. Everything else was negative, yet each physician in turn from one city and another gave the same diagnosis of arthritis. The five years of incapacity were spent in this form of search for relief, finally reaching one of our prominent Southern sanatoriums, and the physician there sent him to me. Here is where I had the advantage, for all necessary examinations had been made and I had the opportunity of making my diagnosis by exclusion, and it was quickly arrived at, for having had other cases of the type, the static wave current was tried at once with the most painful response possible. In fact the patient almost jumped out of the chair when the current was applied to the sciatic notches. Five weeks of sciatic treatment by the use of the wave current restored him to practically a normal state, and this without any applications to the knee joints. These were absolutely ignored, and here is the proof of what I am attempting to place before you for consideration. These cases do not need more than sciatic treatment, unless there is some local tenderness under the testing, and this testing is always desirable.

Leg cramp involving the calf muscles is another type of reflex pain. This comes on after getting warm in bed and is severely painful and not easily relieved by ordinary means at hand. Hot applications will sometimes give temporary relief, but any motion in bed will precipitate an attack.

Cases of this kind that have come to me often give the history of unsuccessful treatments applied to the involved area, sometimes by those physicians working along our lines, and sometimes by physicians in general practice. The fact that the sciatic origin is not

generally recognized makes it come under discussion here. I know of no exceptions to the statement that these are always sciatic in origin, for all of my cases have responded to treatment along this line, the usual static wave current and sparks. First, these cases are thus tested and the treatment follows in course.

The last type for consideration here is that of painful foot, the result of relaxed arches, not flat foot, which latter is an extension of the condition under discussion. In my experience a long standing case of sciatic neuritis will gradually affect the foot and leg muscles and tendons by an enervating influence, if it may be so termed. The nerve nutrition seems to be largely lost and as a result of the superimposed body weight the arch relaxes and temporarily drops while in the standing posture, and returns to its normal when sitting, the pain lessening then. The pain is referred mainly to the juncture of the metatarsophalangeal joints, but may extend to the heel. Sometimes the pain is similar to that from what is known as the Morton toe. One feature of these cases is the fact that the pain is relieved by keeping off the feet, sitting as much as possible when the attacks come on. Occasionally the pain runs up toward the knee but seldom above it. If the usual static wave current test is made to the sciatics, there will be the painful response which is an evidence of the involvement. Fortunately these cases usually respond well to treatment, particularly when the usual electrical measures are accompanied by proper foot exercises. There are some cases that require temporary assistance by the use of felt pads for support of the arch, but these are generally dropped after a time. It will be good practice always to test these foot cases by the method mentioned, for attention to the foot alone will not bring results, if the neuritis is left untreated.

Apologies must be offered for the sketchy manner of presentation of this paper, but the subject is too great for more than passing attention when so many types are given. Even with the lack of detail evidenced here, there is the hope that it will at least bring your attention with renewed interest to the class of cases so little understood by the profession.

Radiological Diagnosis of Secondary Jejunal Ulcers.—S. Gilbert Scott (*Lancet*, July 31, 1926) recommends the following technic when a case of suspected ulcer after gastroenterostomy is being examined:

The patient is instructed to swallow one mouthful only of an opaque barium cream. This is watched passing down the esophagus into the cardiac end of the stomach. It is then taken in charge by palpating hands on the abdomen; and being controlled by this means, the emulsion can be carefully maneuvred through the stoma. The business of the left hand is now to prevent, by gentle pressure, any of the meal passing further into the body of the stomach, for, if the pylorus is passed, shadows in the afferent limb of the jejunum will cause confusion. The business of the right hand is to dam up the emulsion in the first few inches of the efferent limb. This maneuvre is not always easy to accomplish. The opaque cream is now manipulated backwards and forwards through the stroma into the jejunum, and back again into the stomach. This whitewashing process will cause the opaque substance to adhere to any ulcer crater present, showing itself as a black fleck or spot which remains isolated after the displacement of the contents by pressure. This fleck, as in gastric ulcer, shows denser than the surrounding meal. The penetrating type of ulcer is more usual and is easier to detect, as a nipple or budlike projection on the jejunal wall. This will also remain filled after displacement of the contents. Pressure of the right hand is now released, allowing the contents to flow on into the remainder of the jejunum. Six inches from the stoma may be considered the limit of jejunal ulceration. The remainder of the meal is now swallowed and the rest of the stomach examined as a matter of routine.

The author has found that the majority of jejunal ulcers detected radiologically are in the angle formed by the greater curvature of the stomach and the efferent limb of the jejunum (the gastrojejunal angle). The closer the ulcer is to the anastomosis (gastrojejunal ulcer), the deeper it will lie in this angle. The true jejunal ulcer, usually of the penetrating type, is found as a rule projecting from the inner surface of the jejunum, well out of the gastrojejunal angle. Deep pressure in this angle will in many cases help to demonstrate an ulcer.

Those unaccustomed to this examination will at first experience difficulty in detecting an ulcer among the numerous projections and isolated flecks that will be seen in the neighborhood simulating ulcers, and the inexperienced are more apt to see ulcers that are not there than to miss the genuine lesion. The shadow cast by a full meal will mask or overlap the diagnostic features of ulceration, besides rendering full control of the contents difficult. In other words, the whitewashing process described will be almost impossible under this condition, and many small gastric ulcers are still being missed for the same reason. As in gastric work, radiographs alone are of little diagnostic value, most jejunal ulcers being extremely difficult to record on a radiograph, even after they have been located on the screen.

Under present conditions, radiologists should not give a diagnosis of an organic lesion of the intestinal tract unless it has been visualized on the screen—in other words, direct evidence must be forthcoming. The value of the examination is in no way lessened because a distinction between, for example, a simple and malignant ulcer cannot always be discriminated. The hand and eye properly trained are of greater diagnostic value than radiographs, and direct evidence of gastric lesions in nearly one hundred per cent. of cases is, the author believes, possible in the near future if this fundamental fact is but thoroughly grasped and recognized.

Carbon Arc Light in Pediatrics.—Herman Goodman (*Archives of Pediatrics*, August, 1926) remarks that little has been done with the carbon arc in the treatment of the cutaneous disorders of children. With carbon arc lamps, using the socalled white flame carbons or their equivalents, exposures of the child may be made for long periods; there is no danger of painful erythema and burns; the baby's eyes are protected and the child roams about in an open space for treatments as long as twenty minutes to two hours. The author has used this light in impetigo contagiosa, pityriasis rosea, ringworm of the glabrous skin, cutaneous tuberculosis, psoriasis and infantile eczema.

Historical Medicine

Ancient and Modern Lithotripsy.

LOUIS NAGORSKY, M. D.
New York

When civilized man first began the treatment of vesicle calculus, he sought the aid of chemistry, to relieve himself of this condition. Soon, however, he discovered that in order to get immediate relief, he must resort to instrumentation of some kind and so discarded this uncertain method of treatment.

The Egyptians were first to practise the extraction of stones through the natural passages. A description of such an operation by the Arabian physician Haly, for stone in the urinary bladder, was handed down by Proper Albinus. It is as follows: A pipe of ivory or wood of proper size was introduced into the urethra and air blown into the bladder. When the bladder was sufficiently distended, the proximal opening of the tube was tightly corked. With one finger in the rectum, the stone was forced into the vesicle neck.

This procedure was followed by suprapubic pressure and the cork suddenly removed. The force of the expelled air carried the stone along into the posterior urethra and with further dilatation of the anterior urethra the stone was removed. Of course, this applied to small stones. The larger ones were removed in another manner, presently to be described.

The operation of cystotomy is of higher antiquity than lithotripsy. During Hippocrates's time the success of the operation was exceedingly rare, and because of the high mortality this procedure had fallen into disrepute. The reason can readily be understood. Asepsis and modern methods of hemorrhage control were unknown and nearly every one succumbed who submitted to cystotomy.

Ammon of Alexandria employed a sculptor's chisel, when the stone was too large to be delivered through the perineum. He was noted for his great skill and so the term lithotmos or stone cutting was named after him.

During Hippocrates's time, all surgical procedures were considered hazardous and he supposed that all wounds of the urinary bladder were fatal. His reasons were not unfounded because nearly every patient died and he characterized the operation as cruel and murderous.

This induced him to add to his famous set of rules universally known as the "Hippocratic Oath," the paragraph which reads, "I will not cut persons laboring under the stone, but will leave that to be done by men who are practitioners of this work."

As a result of this cystotomy remained in the hands of the latrosurgeons for a long time after Hippocrates. The Greeks under Erros, Megas and others restored this operative procedure to some degree after it had been neglected by the schools. At this time Rome had no lithotomist since no one dared practise it.

Archagatus the first to propose to cut for stone was immediately banished and so cystotomy was not again performed until Celsus, who perfected the method which was used for centuries. So that during this long interval all attempts at extraction of stone through the natural passages were abandoned or forgotten.

Many years after Christianity was established the practice of medicine passed into the hands of the monks.

They would not permit any surgical operation which resulted in loss of blood and so all surgical procedures went under the maxim *Ecclesia Abhorret a Sanguine.*

As a result of this attitude on the part of the church, cystotomy fell into almost universal disuse.

Some time thereafter a group of practitioners known as the barber surgeons developed. These men were restricted in their activities to such operations as blood letting (venesection), removal of corns and other simple and harmless practices.

In the interim, the wretched sufferers from stone were condemned to everlasting misery and received such treatment as lithotriptics and divine saxifrages might offer and which gave no relief till death. Such was the status of surgery at this time.

It was not until the beginning of the sixteenth century that science received a new impulse. A group of lay professors also known as university doctors became numerous and every one began reviving this operation, which lay dormant for so many years.

In those ancient days as well as in our time the question of etiology of stone was as perplexing to the medicos as it is to us. Strange as it may seem, we in our very advanced stage of medical science of today have as little to offer in the way of explanation of the cause or causes, as our ancient colleagues. Their various theories advanced the suggestion that water, food, and other substances were responsible for the formation of stone in the bladder. Our theories are similar and yet we still flounder in the dark and are not positive as to what the true etiology of vesicle stone is.

Ever ready to jump from one method to another for the removal of stone, it sometimes happens that some lay person is inspired to introduce a treatment which often receives universal recognition. Fads of past centuries were just as numerous as present day fancies.

In the eighteenth century a new form of nonsurgical treatment developed in the use of socalled *dissolvements.* A certain Miss Stephens claimed positive cures by her secret method which was advertised as painless and harmless. Her cures were heralded afar with joy and everybody acclaimed her and the wonderful results obtained by her methods. The French government decorated her with a medal of honor and also awarded the sum of sixty thousand francs. No more operations, no more suffering. The enthusiasm became so great that lithotomy was barred.

Whenever mucus was found in the urine, it was thought to be dissolved stone. The treatment con-

sisted of drinking copious drafts of lime water and soap, which was supposed to dissolve the stones or prevent their formation.

Soon joy changed to sorrow and enthusiasm waned, because it was discovered that this sure cure was

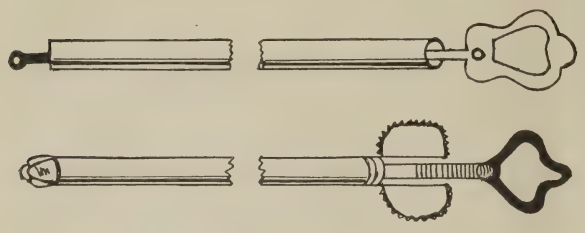

Fig. 1.—Eighteenth century lithotrite.

nothing else than a chimera and so it went the way of all other such procedures.

The introduction of the straight sound was known ages ago. These sounds were found in Herculaneum and are still to be seen in museums of antiquity.

In 1561 Franco devised a four branched instrument which he called the *quadrupulus vesicæ*. This instrument could grasp a stone the size of a hen's egg. The disadvantage of this instrument is appar-

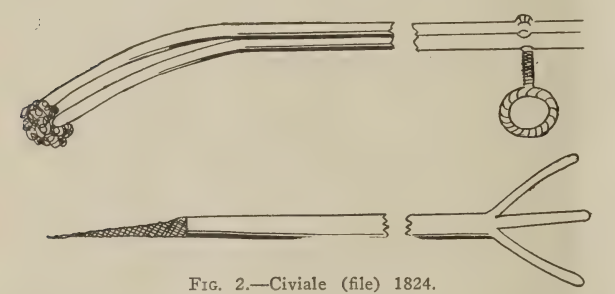

Fig. 2.—Civiale (file) 1824.

ent because it could be passed only through a large perineal incision.

A period of quiescence elapsed when the curved sound appeared. Daniel Episcapus left such an instrument.

Sanctorius, in the seventeenth century, extracted small calculi by means of an instrument he devised which consisted of a three branched forcep. The larger stones he crushed with a stilette.

A rectilinear sound was demonstrated in 1813 by one Dr. Gruithuisen of Munich.

In 1819 Mr. Elderton, of England, invented a curved thick sound. At the head of the instrument

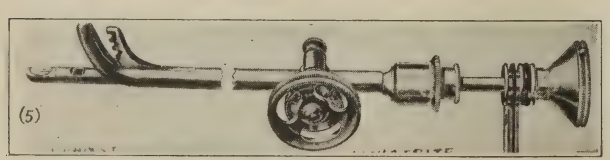

Fig. 5.—Lohnstein (Berlin) cystoscope lithotrite.

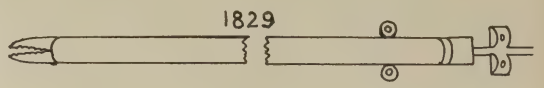
was attached a handle and the vesicle end contained two branches.

Sir Astley Cooper, the famous English surgeon, in 1821, reported a case of extraction of calculi. In this operation he used a common forceps, the size of a sound and curved similarly to a bullet forcep. The instrument was passed into the bladder and the operation performed this way. He succeeded in removing eight stones.

A French surgeon operated on a monk for stone in the bladder. He passed a funnel catheter into the bladder and through this a sharp chisel. By striking gently the outer end of the chisel small fragments were removed and washed out.



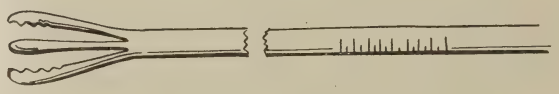


Fig. 3.—Vesicle stone measurer.

From the days of Civiale, the great French surgeon who devised the Triblade (1824) (an instrument consisting of a drill, a central axis and three claws) to the year 1878, little or no change in the operation was observed. In those days rapidity and skill were all essential. Operations were limited in time to three minutes to avoid cystitis. This was a complication to be dreaded and one of the important reasons for the slow development of the lithotrite. Weiss improved on the instrument and constructed what he called the Triblades; a crushing instrument. (Civiale's instrument was not a crushing instrument.)

It was left to Bigelow to revolutionize the whole system. His perfection of the instrument known as the Bigelow lithotrite and his evacuator enabled the surgeon to successfully remove all the crushed fragments of stone in one sitting. His improvement on the handle and lock and the change from a solid "female" arm or crushing end to a fenestrated one, completed a nearly perfect instrument.

This (Bigelow) lithotrite[1] has been in use for

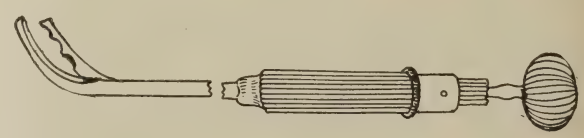

Fig. 4.—Bigelow lithotrite 1878.

many years and also has had its rise and fall like all other instruments. It served its purpose in chosen cases and in skilled hands was a very effective instrument. Its sole disadvantage was the fact that the operator had to work in the dark, so to speak. Withal, a dangerous instrument in the hands of the inexperienced and unskilled. The dangers were the possibility of penetrating the bladder wall or of tearing out a piece of bladder mucosa during the process of stone crushing.

In the hands of a skillful surgeon this operation, like all other operations requiring skill and expe-

[1]Chismore's improvement on the Bigelow lithotrite, consisted of a hollowed made blade. This permitted irrigation of the bladder, without removing the lithotrite.

rience, was devoid of many of its dangers. Care had to be observed in the introduction of the instrument through the urethra and into the bladder.

So with the passing of other obsolete instruments, the Bigelow lithotrite must join its everswelling ranks and make place for its latest rival, the cystoscope-lithotrite.

This consists of a lithotrite and cystoscope combined. The body of the lithotrite is tunnelled and permits of passage for the obturator. After the instrument is inserted into the bladder, the obturator is removed, the bladder filled with a solution of boric acid or any other antiseptic fluid, and the telescope substituted. This enables the operator to get a clear vision of the interior of the bladder and its contents. The stone is easily caught between the jaws of the lithotrite and crushed. No longer is it necessary to perform this operation in the dark, thanks to the genius of the inventor of the cystoscope-lithotrite.

This now brings to a close this rather hurried and superficial description of the history of the lithotrite. A more fascinating chapter of surgery does not exist and much credit should be bestowed upon the geniuses who were instrumental in developing the lithotrite to its present perfection; from a simple crude tube to the wonderful modern cystoscope-lithotrite.

Indications for the cystoscope-lithotrite included such patients who will not submit to an abdominal incision, such as suprapubic cystotomy calls for. Diabetes is another strong indication for lithotripsy. Stones not too large should be crushed by the cystoscope-lithotrite.

The advantages are many and important. Convalescence is short as the patient in many instances is enabled to attend to this business without loss of time and inconvenience. There are no wounds to heal and as stated above, recovery is rapid. Of great importance is the lack of danger from secondary hemorrhage.

Most important factor in this modern method of cystoscope-lithotripsy is that the whole operation is done under actual vision.

Of course, where the stone is very large, suprapubic cystotomy should be the choice of operation. Also in certain cases of middle lobe hypertrophy of the prostrate.

Local anesthesia with cocaine or novocaine in the urethra is all that is necessary in many cases. General anesthesia may be decided upon in neurotics or such patients as would prefer such anesthesia. The most common practise at present is sacral anesthesia.

Before introducing the lithotrite, a careful examination of the urethra should be made. If the meatus is too narrow a meatotomy is indicated.

If stricture of the urethra is dilatable stretching it up to the size of the instrument (lithotrite) should be done. Should the stricture be filiform in size and tortuous in character, all attempts at lithotripsy should be abandoned and a cystotomy done instead.

In former times the method of locating a stone in the bladder was very crude and was performed by introducing the stone finder and manipulating the instrument in the bladder until it struck the stone.

X ray does not always help because certain stones do not photograph. The most positive diagnostic means at our disposal is the cystoscope. At present, with the combination of both cystoscope and lithotrite, we have an instrument which is both diagnostic and surgical and offers a means of rendering the operation of stone crushing in the skilled operator's hands, simplified and yet complete. It has a decided and important place in the practice of surgery and should be used more often.

The operation of lithotripsy *per se,* barring a few remote accidents, like the fracture of the crushing end of the lithotrite (as was reported in a recent case with the use of the Bigelow lithotrite) is not a dangerous procedure, especially with the cystoscope-lithotrite, and judging from the experiences of others and myself is far more safe than cystotomy.

In conclusion, I wish to add a statement taken from a Study of Vesicle Calculus at the Mayo Clinic:

"Litholopaxy was performed in 153 cases (138 men and fifteen women) and suprapubic cystotomy in 395 cases (385 men and ten women). The mortality in litholopaxies was 1.3 per cent. and in cystotomies 8.7 per cent."

Contributors to the Science of Medicine

John Radcliffe

While Radcliffe was stigmatized by his rivals as the physician without learning, and many were jealous of his success, and enraged by his rude ready wit, at least he was a common sense practitioner, and one of foresight. In the period in which he lived the custom of the profession was to bleed vigorously and persistently, and to drench their patients with slops, caudles, and diet drinks, in fact, to lower their powers of resistance by every possible means.

The methods of Radcliffe were rational. He eschewed the devitalizing measures in vogue and based his treatment mainly upon fresh air, personal hygiene, and by the administration of simple and therefore harmless remedies. Radcliffe was eminently a practical physician who relied chiefly upon experience in an age when empirical treatment

founded largely upon the writings of long dead physicians held full sway. He acknowledged Sydenham as his master and followed his precepts faithfully. His was not an original mind but one distinguished by strong good sense and natural sagacity. Radcliffe's chief claim to rank as a contributor to medical science rests upon his munificent gifts for the endowment and advancement of medical science during his life and his yet larger posthumous generosity for the same purpose. In this respect his liberality was unexampled and warrants fully his inclusion in the niche of fame as a great contributor to the progress of medical science.

John Radcliffe was born in 1650, his father possessing a moderate estate in Yorkshire. John did so well at school that he was sent to Oxford University at the age of fifteen. In spite of the sneers of his jealous contemporaries that "he had no learning" he was made senior scholar of his university college and in due time took the degree of B.A. and was made a fellow of Lincoln College. He became M.A. in 1672, it is said with uncommon applause. In the meantime he had been pursuing diligently the study of physic and attending the various courses of anatomy, chemistry and botany delivered in the university. In 1675 he became Bachelor of Medicine and immediately began to practise in Oxford with great success. He probably gained the complete confidence of the public by his judicious mode of treating smallpox, a method introduced by Sydenham ten years previously. It consisted in the employment of the cooling treatment, the practice of the time being to keep the patient in a hot close room from which all fresh air was rigidly excluded. Few of his contemporaries approved of the practice of Sydenham, the new method indeed had the sanction of John Locke, but for the most part the practitioners of the day continued to trudge along in the footsteps of their forefathers. Smallpox was raging in Oxford when Radcliffe was there and instead of confining his patients in a stifling room, as was done by other medical men, he employed this new method, exposing the sick to the free access of fresh air, giving them cooling emulsions and using other antiphlogistic remedies. This treatment was followed by immediate and remarkably beneficial results and set the seal upon Radcliffe's fame. Indeed, he had been practising only two years in Oxford when all the most prosperous families within reach of the city sought his medical aid.

In 1652 he took the degree of Doctor of Medicine. When thirty-four years old he moved to London and had not been there for more than a year before he rose to the head of his profession and received in daily fees the sum of twenty guineas, about $105, which would be worth now at least twice that amount.

Radcliffe was a man of good presence, endowed with great powers of conversation, and of a ready albeit coarse wit in keeping with the times. In 1656 he was appointed physician to Princess Anne of Denmark and was for some years a trusted adviser, but he lacked the courtier's compliancy and suavity. The Princess Anne, having brought on the condition termed by the vulgar "blue devils" from not paying proper attention to her diet, sent in all haste for the physician. Radcliffe, a *bon vivant,* when he received the royal command, was sitting over the bottle in a tavern, also a custom of the times. He was loath to leave the allurements of Bacchus and stayed on. A second messenger arrived but then Radcliffe was so greatly under the influence of the heady beverage that he allowed his "Dutch courage" to overcome his discretion, and refused to go. "Tell her Royal Highness," he shouted, banging the table with his fist, "that her distemper is nothing but the vapors. She's in as good a state of health as any woman breathing —only she can't make up her mind to believe it." He repented of his rashness when the fumes of liquor had been dissipated but Anne never forgave the sarcasm as to "the vapors" and Radcliffe was no longer her physician. This rupture with Princess Anne, however, made no difference to his popularity with the public and he continued to have the most lucrative practice in town.

When King William of Holland and his English wife, Mary, came to the throne they brought with them the Dutchman, Dr. Bidloo, as chief physician. But this did not injure the fame of Radcliffe. Bidloo, who was an able physician, in consequence of his comparative ignorance of the English language and of English constitutions created a certain amount of distrust. Radcliffe attended two of King William's Dutch favorites who recovered rapidly under his care and he became the King's physician. However, the King did not follow his physician's advice and Radcliffe was called in to see him. In reply to some questions, the King, showing his swollen ankles, which formed a striking contrast with the rest of his emaciated body, exclaimed, "Doctor, what think you of these?" "Why truly," said he, "I would not have your majesty's two legs for your three kingdoms." This illtimed jest had the same effect as his rudeness to the Princess Anne; it terminated his professional attendance at the Court of William. At the death of William, which took place shortly after this incident, an attempt was made to overcome the repugnance which was felt towards Radcliffe by Queen Anne but in vain; she replied to the inducements of her friends, that he would send her word again that her ailment was nothing but the vapors. Yet so much was his knowledge and ability respected that on the various occasions of the Queen's illness his advice was resorted to frequently, and he was rewarded most liberally for his opinions and prescriptions.

Radcliffe was a man at one time guilty of almost incredible meanness in money matters and at another time capable of munificence apparently on a scale beyond his wealth, and he also exhibited a stoical fortitude under any reverse of fortune that chanced to deprive him of some of his cherished lucre. His liberality to Oxford was by no means all of the post-mortem variety. In 1657 he presented the chapel of University College with an East window. Of the many instances of how his nature could "do good by stealth and blush to find it fame" his generosity to James Drake, a political writer as well as a physician, may be mentioned. Each of these men had tried their utmost to injure the reputation of the other. *But* when Drake, broken by political persecution, was sorely in need of money Radcliffe put fifty guineas— more than $250—into a lady's hand and begged her to convey it to Drake. "Let him," said Radcliffe, with the delicacy of a noble disposition, "by no means be told whence it comes. He is a gentleman, and has

often done his best to hurt me. He could, therefore, by no means brook the receipt of a benefit from a person whom he had used all possible means to make an enemy."

Radcliffe was sent for to attend the Queen in her last illness but was prevented from doing so by being confined to his house in the country owing to an attack of gout. The Queen died and so great was the faith in Radcliffe's skill that his absence from her sick bed was publicly regarded as the cause of her death, or rather it was believed that had he been present her life might have been saved. So strong was public sentiment in this direction that a member of Parliament, of which Radcliffe was also a member, went so far as to move four days after the Queen's death that Radcliffe should be summoned to attend in his place, in order to be censured for not waiting upon her in her extremity. The feeling against the doctor rose to such heights that a set of maniacs formed a scheme for his assassination. Fortunately, however, the plot was made known to him. His end was hastened by mental disquietude and he died on November 1, 1714, three months after the death of the Queen, according to his earliest biographer, "a victim to the ingratitude of a thankless world and the fury of the gout."

As a practitioner Radcliffe deserves the greatest praise and the gratitude of future generations. The violent measures of bleeding, and the administration of reducing medicines carried to an almost unbelievable extent in his day, he regarded with distrust in most cases and with horror in others. He, perhaps, was the brief factor in the abolition of this system. No doubt one reason why he deservedly gained so great a reputation was because his methods of treatment were not only more pleasant but were found by experience to be more effective by far than the methods prevailing. A good story is told of his rough and ready way of illustrating his disapproval of the kill or cure system and his hatred of Dr. Gibbons, nicknamed by him Nurse Gibbons, one of the most prominent exponents of the system. John Bancroft, a well known surgeon, had a son attacked with inflammation of the lungs. Gibbons was called in and prescribed, as was his wont, the most violent remedies, or rather the most virulent irritants. The child became rapidly worse, and Radcliffe was sent for. "I can do nothing, sir," he said, after visiting the patient, "for the poor little boy's preservation. He is killed to all intents and purposes. But if you have any thoughts of putting a stone over him I'll help you to an inscription." The offer was accepted, and over the child's grave, in Covent Garden churchyard, was placed a stone sculptured with a figure of a child laying one hand on his side and saying *"Hic dolor* (there is the pain) and pointing with the other hand to a death's head on which was engraved, *Ibi medicus* (there is the doctor)."

Numerous witty sayings originated with Radcliffe. It was the age of wits, among whom some of the doctors held their own; Arbuthnot, the wittiest of all medical men, Garth, Blackmore and Radcliffe even when pitted against such giants as Addison, Steele, Swift the terrible Dean of St. Patrick. Towards the conclusion of his life Radcliffe said that when a young practitioner "he possessed twenty remedies for every disease; and at the close of his career he found twenty diseases for which he had not one remedy." Despite this statement, which is probably true of every practitioner, his mode of practice at the outset, as far as is known, was the same as that which he used at the end of his career. Pure air, cleanliness and a wholesome diet were his main prescriptions. For the imaginary maladies of his hypochondriacal male and fanciful female patients he had the most supreme contempt, and neither respect for age or rank, nor consideration of interest could curb his bitter tongue when referring to such patients. The case of the Princess Anne is one in point.

At one time he lived in a house adjoining that of the great painter, Sir Godfrey Kneller. Sir Godfrey accorded Radcliffe the freedom of his lovely garden, which kindness was so abused by the servants of Radcliffe that the painter protested to their employer and threatened that if the annoyance continued that he would brick up the wall. "Tell Sir Godfrey," answered Radcliffe to the messenger, "that he may do what he likes to the door, so long as he doesn't paint it." When this vulgar jeer was reported to Kneller, he replied with equal good humor and more wit. "Go back and give my service to Dr. Radcliffe, and tell him I'll take anything from him—but physic."

Although Radcliffe had his foibles, eccentricities and vices, these were the vices of his station in life and the times; he was essentially a man and of independence and vision. As a contributor to medical science, he was a pioneer of the reform of an obsolete and harmful form of medical practice, one that was steeped in ignorance and fostered by tradition and convention. Radcliffe, at least, had rational views of practice and was a devoted follower of Sydenham, who did more than any one man to place treatment upon a sound foundation.

However, as said before, Radcliffe's chief claims to fame rest on his magnificently generous gifts for the advancement of medical science. By his will be left his Yorkshire estate to the Master and Fellows of University College, Oxford, in perpetuity in trust for the foundation of two traveling scholarships, the Radcliffe medical scholarships. To St. Bartholomew's Hospital he gave the yearly sum of £500 forever, towards mending their diet, and the further yearly sum of £100 for buying of linen; £5,000 for the enlargement of the building of University College, Oxford; £40,000 for the building of a library at Oxford; and when the library should be built £150 per annum to the librarian, and £100 per annum for buying books. After the payment of these bequests, and some legacies to various individuals mentioned in the will, he gave to his executors in trust all his estates in Buckinghamshire, Yorkshire, Northamptonshire and Surrey, to be devoted to such charitable purposes as they all in their discretion should think best. Besides the Radcliffe Library which was finished and opened in 1749, the observatory and public Infirmary at Oxford were built from these funds. In 1825 the trustees gave £2,000 towards building the College of Physicians in London and towards defraying the cost of erection of the Oxford Lunatic Asylum, opened in 1827.

Radcliffe's memorial is the splendid library and other buildings in Oxford which bear his name. It cannot be said that Radcliffe was not conspicuous in the advancement of medical science.

Editorial Articles

MAN AND THE SOIL

It is an axiom that those human beings who live under conditions the closest to nature are the most healthy. It does not follow, of course, that they are the most immune to disease, those who live in cities and in industrial centres become immunized to disease to a large extent, but the country dwellers who are the least civilized are comparatively free from those diseases which abound in urban districts and which are almost unknown among primitive people. The more primitive a people, the more robust their physical characteristics. Also, and this is the point upon which it is desired to place emphasis, that race which live on the produce of their own soil are more healthy than those who import their food. There is no doubt whatever, that artificial and canned foods are less nutritious than the fresh products of the soil and it, moreover, seems reasonable to suppose that food grown on the soil of the country or district in which an individual lives is best for him. The question of diet is all important and well to the fore in these days. It is recognized that overindulgence in food and drink brings about premature senescence, deterioration of the tissues, old age being as much a matter of worn tissues as of years, and premature senescence renders one prone to the attacks of disease. Therefore, frugality in eating and abstemiousness in drinking are important factors in keeping the tissues in good condition and warding off old age and disease.

In the book by Ettie Rout, recently published by William Heinemann, London, native diet is discussed. The author, who is a native of New Zealand and who lived there for many years, deals with the diet of the Maori, but her remarks apply with practically equal force to most native diets. In the introduction attention is directed to the fact that natives such as the ancient New Zealand Maori habitually took food for life and health, while civilized peoples frequently take food merely for amusement and enjoyment. With the Maori indeed food was medicine, and a large part of the diet was fresh green food.

The argument running through the book is that no nation can be really healthy and can endure for long unless, as a rule, it grows its own food supply. No nation has ever lasted which failed to conform with this primary essential of permanency of life. It is in truth a case of man and the soil. In mother's milk there is an elusive substance which makes of it the best food for the infant and the reason why so many babies are unhealthy and do not reach adult age robust and vigorous is because they have been denied their natural food of mother's milk. May not there be a something in the soil upon which a man is reared that like mother's milk renders food grown on that soil the most nutritious and invigorating for him? That too much stimulating and sophisticated foodstuff is eaten nowadays is undeniable. While in industry wealth may be found, in agriculture health will be found. Wealth without health is a mere irony, and the country which depends upon industry and neglects agriculture is doomed to decay individually and racially. Man and the soil are related so intimately that divorced from the soil and fed on canned and storage food and not on that fresh from the soil and grown in the soil he deteriorates inevitably and in course of time must yield the pride of place to the man who has been reared and brought up on natural food and the fruits of the soil.

A FORGOTTEN WORTHY

We are indebted to Dr. John E. Lane for introducing us to one of the illustrious forefathers of medicine with whom we, and we believe most other physicians, were not familiar. From medical history we learn humility and, at the same time, derive encouragement. We are humble before the prophets in medicine and what they accomplished and can rejoice over the improvement healthwise which has taken place since their days. Especially is this true in reading this painstaking and scholarly sketch of Robert Willan, for Willan was not only the "founder of dermatology in England" but one of the apostles of public health in that kingdom.

Willan lived from 1757 to 1812. Like not a few great men interested professionally in health and disease, he was of delicate constitution, but by great care achieved "an uninterrupted share of moderate health."

His rise in reputation seems to date from his appointment in 1783 as physician to the new Public Dispensary in Carey Street, London. He developed a clinical school in which kind of teaching he was eminently successful. He produced a classification of cutaneous diseases which was followed by most English physicians for a half century.

He made an historical study of smallpox which was considered "epoch making." His description of the "Characteristics and Effects of Perfect Vaccination" are said by Lane to be "models of vividness and lucidity that can hardly be improved on." He was outspoken on the importance of fresh air treatment and was equally bold in proclaiming the value

of bathing in all eruptive diseases including smallpox.

This leads to the public health view of the times which we gain from Willan's writings. He said:

"By a strange thoughtlessness, most men resident in London, and very many ladies, though accustomed to wash their hands and faces daily neglect washing their bodies from year to year. Hence the perspiration, condensed on the skin, gradually obstructs the exhalant pores, thereby producing various internal complaints, and an universal itching over the surface of the body, to which some delicate sufferers reconcile themselves, by supposing a scorbutic disposition communicated from their progenitors, without any fault of their own. Itching eruptions on the skin, often denominated Scurvy, or the English Malady, will never be eradicated until bathing or washing in warm water becomes general. The introduction of it, however, is not likely to be the work of physicians or philosophers alone. They must first influence the leaders of fashion. Let some of our nobility erect baths . . . in their spacious mansions, and, by setting an example, induce others to make the practice of bathing habitual. The custom would soon be adopted in every part of the metropolis."

With regard to vaccination he wrote to Jenner in 1806:

"Time and experience now allow me to draw the following conclusion from the history of Vaccination in our own country—that wherever it has been much practised, there the Small-pox is least seen among the inhabitants, and wherever it has been universally practised, there it is not seen at all, and if brought by accident, that it does not spread. . . ."

Referring to chlorosis he wrote:

"Young females are often affected with it, who follow a sedentary occupation in close streets, or narrow, crowded tenements, and seldom enjoy the benefit of fresh air. The disorder is not, however, confined to this class of people. We cannot be surprised that young ladies of the highest rank should suffer equally; eight months of the year they sit on thick carpets in close rooms heated by register stoves; have large fires kept in their bedrooms, never stir out except in carriages, and are often too much restricted in their diet. The weakness and extreme irritability induced by this mode of living not only brings on the chlorotic state, but after the slightest exposure to damp, or cold air, renders them also liable to be affected with pains and inflammations of the bowels, rheumatism, head-ache, catarrh, phthisis, etc., more especially as in the article of dress at that period of life, health is always sacrificed to fashion."

Lane concludes: "Willan was one of the important founders of modern medical science. In the words of Chaplin: 'We owe to the physicians of the age of George III an immense debt for the excellent foundations they built, often with rough and improvised tools. Men of the stamp of Hunter, Baillie, Prout, and Willan flung open the portals of medical science, through which their descendants have passed to realms of spacious and accurate knowledge.' Willan shared the physician's fate. The memory of the man himself was soon lost. For the conscientious physician, 'The reward of a thing well done is to have done it. The fruit of a good service is the service itself.' Willan earned this reward. In addition to this an unknown contemporary said of him that he 'left engraven on the hearts of a chosen circle, praise far more valuable than monuments of marble.'"

Those who will be interested to read the fine essay in full will find it in the *Archives of Dermatology and Syphilology* for June, 1926.

THE RISING TIDE OF DEGENERACY

According to Albert Edward Wiggam, whose *Fruit of the Family Tree* has made his name favorably known to all interested in eugenics, the blood of the nation is flowing in the wrong direction, which means, if continued, its ultimate downfall. "It is flowing from the country, man's natural habitat and breeding ground, into the cities, where the fires of luxury and ambition consume the nation's cradles; it is flowing from the common and subcommon to the supercommon classes, where again its precious leaven is licked up by the same devouring flames." . . . "In addition, charity, hygiene, sanitation and the triumphs of chemical, biological and medical genius have preserved for reproduction great numbers of incompetents and defectives who in the good old days of natural selection would have died young. Civilization is thus seen to be a selfdestructive enterprise, the most dangerous enterprise upon which mortals ever set out, and one which, by its very nature and objective, sets going those agencies which in the end destroy the men that built it and insures its own destruction."

But Mr. Wiggam is not so hopeless as his introduction would indicate, for there is a way out he thinks, and that is intelligent eugenics. He quotes abundant proof of the transmission of hereditary traits and the ill effect that heredity now exerts in increasing crime and delinquency. He urges the need of an intelligent choice of marital partners and believes there has been a material awakening on the part of the intelligentsia, at least, to this need.

This alone, however, will not effect the salvation of the race. We must not alone promote the propagation of the intelligent and the moral classes—and he finds that intelligence and morality go hand in hand—but we must curb the propagation of the imbeciles, the weaklings, the degenerates, and the criminal. He urges the further extension of the practice of sterilizing imbeciles and morons. Many will be surprised to learn that there are twenty-two states which now have sterilization laws which are rapidly being made effective. . . . Up to 1926 California had sterilized 4,500; Kansas, 335; Nebraska, 260; Oregon, 313; Wisconsin, 144; Indiana, about 700;

Michigan, about 100. "But the high birth rate among the poor is objectionable aside from the question of heredity because it increases the number of the poor. The way out of this is, he thinks, the spread of the knowledge of birth control." So far any knowledge of birth regulation has been the possession exclusively of the educated and the well to do. But when it becomes a matter of common knowledge, when moron and genius, pauper and prince can alike determine whether they will have one child, or none, or half a dozen, the question of all questions in both our national and our racial fortunes will be, who is going to assume the burden of parenthood? He hopes that the more intelligent and well to do will.

THE INDIAN MEDICINE MAN MUST GO

Dr. Hubert Work, Secretary of the Interior and former president of the American Medical Association, contributes to *The American Review of Reviews* an interesting study of the Indian medicine man. It seems that these charlatans still have a large following among the Indians and are responsible for much of the friction between the United States officials and the Indians. It will be remembered that Sitting Bull, the Sioux chief who was responsible for the Custer disaster, was a medicine man, a large part of his power as a leader being due to that fact. Dr. Work quotes the following from a report submitted by a physician of the Indian Medical Service stationed in Arizona:

"Get rid of the medicine men and the Indian Office will make more progress in one year than it has heretofore made in any ten years. This would be as true of many other tribes as it is of the tribes under this jurisdiction.

"The Indians have a strong natural inclination and desire to cling to their old habits and customs. This being true, it is reasonable to suppose that so long as they have leaders of their own race who also believe in holding to the things of the past, to whom they may look for advice and counsel, they will be hindered in their progress. It is impossible to serve two masters. They cannot follow their superstitious and backward leaders and make progress under the Government program of education at the same time. The Government can never gain their full confidence so long as their mentality is subjected to the retarding influence of the medicine men.

"The medicine man thrives on ignorance and superstition; consequently, he does all in his power to keep the people from patronizing the Service physicians. He threatens to haunt them and bewitch them, and he sends out his vassals to warn them of the dire disasters to be visited upon them if they fail to render him obedience and homage and do not cease taking up the white man's ways. This makes the successful practice of scientific medicine most difficult among Indians.

Dr. Work holds that Congress, which now prescribes qualifications for the Service physicians, should also insist upon such qualifications for Indian doctors as would at least prevent their contributing to the death of their patients.

GOITRE AND PHYSICAL DEVELOPMENT

The whys and wherefores of endemic goitre are by no means as easily answered as one might suppose and some of our conclusive guesses from small knowledge are not confirmed by investigation.

We mentioned in these pages recently the negative results of a study of the effects of goitre on the intelligence of school children in the schools of Cincinnati made by the Public Health Service. A study of the relation of goitre to physical development was carried on also in the Cincinnati schools and is just made public. Considering the supposed influence of the thyroid upon normal growth, one would expect to find evidence of this where goitre is considered relatively frequent. The comparison of the measurements of children in the Cincinnati schools with and without goitre (or apparent evidence of goitre) seems to prove that better nutrition and posture are slightly more frequent among thyroid-normal boys and girls. There was little difference in height between thyroid-normal and thyroid-enlarged boys, but the height of girls with normal thyroid was greater. However, the average sitting height was consistently greater among both boys and girls with thyroid enlargement. The average weights of both the boys and girls with normal glands was greater. Underweight was more frequent among those with thyroid enlargement.

The investigators conclude: "Whether the results of this examination of a relatively small number of children indicate a constant, uniform, and significant difference in physical measurements of normal and thyroid-enlarged persons can be ascertained only by further and more extensive investigations of similar character. Certainly the findings are suggestive and indicate the need for maintaining a normal thyroid gland lest a retarding influence be exerted upon physical growth."

With regard to the cause of goitre it has been pointed out lately that even in regions of Switzerland where cretinism is frequent, a large proportion of the inhabitants not only escape this condition but have apparently normal thyroids and a hereditary factor would seem to enter into the problem of etiology. Certainly there would seem to be some factor at work other than lack of iodine, or, in some regions of our own country goitre would not be confined to a certain percentage but would exist in the whole of the population.

It has already been pointed out in these pages that goitre or what is said to be goitre, is being found to be comparatively frequent in communities near the seashore. There is much still to be learned about this subject.

THE OLD PERSON

With unusual foresight there has been of late some special consideration given to the needs of health preservation of the elderly person, as though human kind were living to a more advanced age and were, hence, in need of such specialized medical attention. We hear much these days about the lengthening of the span of life, but, while it is true that more people live longer than formerly, the maximum years of the individual are not greater, even if a few more persons do attain to three score and ten years or so. We do not need to prepare to preserve centenarians, though it is well if we can make the later years of the many who now attain anywhere on the postmeridian side of life, happier.

It is difficult to define old age. As we have physiological and chronological age in the young, so we have physiological and chronological age in the elderly. Every clinician has been struck with the advanced physiological age of persons hardly more than fifty, and equally surprised at the bodily preservation of those of seventy or more years. Heredity doubtless sets its limits of tissue health and longevity, while, on the one hand, hardship and bad habits join hands to destroy and, on the other, ease and temperature tend to preserve, and to prolong life.

When one examines the statistics of any industry or profession he is struck with the rapid decline of the number of persons employed in the heavier occupations for the decade beyond fifty, and there is no doubt that the use of labor saving machinery is one of the factors tending to prolong existence. Doubtless the stress and strain of heavy toil told especially on the circulatory system, both on vessels and heart, and death from these causes cut short a larger percentage of lives before they had attained to what would now be called old age. In the good old days when men burdened their circulatory and excretory organs with heavy drinking and as heavy eating, sixty was considered a quite advanced age.

One may be as old as his arteries, for arterial degeneration certainly makes living a precarious business. Experiments on cadavers show that the arteries of the brain will stand four times the normal pressure, provided they are healthy, and with health there should be no premature passing away from apoplexy. Superfluous feeding and arterial degeneration seem to go hand in hand, but feeding is often the chief pleasure of the aged. A reduction of food becomes a matter of swapping minutes or hours of pleasure for days or years of mere stupid existence, and many would prefer the former.

Feeding is not so much the end of existence where there is some other end, and it is exceedingly important that the elderly person should not be cut off prematurely from work and from absorption in varied interests outside himself. The decline of many men who have retired from business needs but mentioning.

With decrease in neuromuscular activity goes decline in activity of the intestinal tract and it comes to be one of the services of the physician to stimulate this function. Fortunately there are drugs which help in this direction over a period of years without apparent injury.

For "busy work" reading was, until lately, about the only solace of the aged, and it is important that everything should be done to give him the best vision possible. The radio has been a godsend to the elderly with impaired vision and cannot be too highly recommended as an agency conducive both to longevity and enjoyment of life.

The automobile is another help to the old, by not only furnishing harmless exercise but by giving added interest to life and by affording exposure to air and sun. Such agencies go farther than all the drugs of the pharmacopœia in maintaining health and prolonging life and the physician should have them in mind, for often they do not occur to thoughtless, though anxious, younger relatives. Even the crossword puzzle has been good medicine for many elderly persons.

In case of evident weakness or illness, examination of the elderly cannot be too careful, for they are singularly unreactive. As an instance a case was recently reported of a total right pneumonia found at autopsy in an elderly woman who had not complained of symptoms. If examination in the aged should be careful it should also not be wearisome, for even in younger persons too much examination has been the last straw in the balance on the side of fatal termination. Professional interest (or even "science" —whatever that happens to mean) should not stand before the welfare of the patient, young or old.

Obituary

ROBERT F. McGINNESS, M.D.

Brooklyn

Dr. Robert F. McGinness died of heart disease at his home on Jefferson Avenue, Brooklyn, on October 24th at the age of fifty-four. He was a native of New York City and received his medical degree from the University of Baltimore in 1898. He has been in practice in Brooklyn ever since 1899.

Royal Victoria Hospital, Montreal

Annual Clinical Congress of American College of Surgeons

(*Concluded from page* 651)

As noted in the previous issue Macewen and his great immediate predecessors in office were important factors in the development of the Glasgow school. Professor Young is admirably competent to tell of the Glasgow School of Surgery and of one of its great makers, at any rate, as he was Macewen's assistant for many years and his successor as Regius Professor of Surgery.

Before proceeding with the subject he knew so well Professor Young paid sincere and humble tribute to John B. Murphy as one of the pioneer surgeons of the world and acknowledging that to his researches are due some of the greatest beneficent revolutions in surgery ever witnessed. However, he only knew of the work of Murphy and had never known or even met the man, he therefore acted wisely in selecting for his theme a wonderful surgeon whom he knew as intimately, perhaps, as any one knew Macewen as he was a Scotsman of an inviolable habit of reserve, the inner man was seldom disclosed.

The School of Surgery of Glasgow dates back to 1598 when the famous Maister Peter Lowe returned from France to his native Glasgow, he like Ambroise Paré, but no doubt for different reasons, having escaped the perils of the Massacre of St. Batholomew and obtained after four years' endeavor the charter for the Faculty of Surgeons of Glasgow. The Regius Chair of Surgery of Glasgow University was instituted in 1815, and Professor Young gave biographical sketches of the five professors who had occupied the chair previously to himself. Of these James A. Lawrie held office from 1850 to 1859 and was responsible for a great advance in cranial surgery. Glasgow still remembers him with pride. Joseph Lister was appointed to the chair in 1860, and held it until 1869, and of him Dr. Young said, "What I may be permitted to call the Lister tradition is more than sufficient to render the Regius Chair of Surgery in the University of Glasgow illustrious for ever. Viewing surgery as a science he was probably the greatest surgeon of all time and one of the memories which I cherish is that of shaking hands with the immortal Lister on the one occasion when I saw him and Sir William Macewen was the fifth Regius Professor was appointed in 1892 and held office until his death in 1924. Macewen was described by the speaker as a man of quite extraordinary energy finding or making time in his busy life to write more than seventy treatises and books. According to Young, Macewen's genius seems to have been founded on a cultivated ability and determination to carry on everlastingly in his labor for surgery and surgical pathology. Further, he had a faculty for taking full value out of every part of his work, no matter in what line his energies were employed for the time. There always seemed to present themselves some problems on which he could exercise his active brain.

Macewen, said Young, was a selfconfident, self-

sufficient man, who was somewhat distrustful and skeptical of views which he had not thoroughly analyzed himself. He cultivated in himself and advocated for his students the spirit of philosophic doubt, thus prompting many questions and keeping the teacher forever on the alert. Three special aspects of his great life work were his share in the development of modern aseptic surgery, his work upon bone and his pioneer work upon the surgery of the brain and spinal cord.

Dr. M. T. McEarchen, Chicago; Dr. Bowman C. Crowell, Philadelphia; Dr. W. W. Chipman, Montreal; Dr. Franklin H. Martin, Chicago; A. D. Ballou, Chicago; Dr. Allan Craig, Chicago, Officials of the Congress.

As to the question whether Macewen or Horsley was the actual pioneer of modern brain surgery, it had not been decided, Young pointed out, that that honor is due to Macewen, but as he further justly stated that both were prompted in this direction by the investigations of Hughlings Jackson and others. Macewen's classic work on *Pyogenic Diseases of the Brain and Spinal Cord* was published in 1893 and still remains a standard work.

In closing his address Dr. Young told the audience that the inaugural memorial Macewen Lecture will be delivered next year by Dr. Harvey Cushing, of Harvard University Medical School, and he also said that Macewen had many offers from universities and medical schools in the New World and especially from Johns Hopkins. But he felt that he had work to do which would be interrupted by a chance and he felt that this was of greater importance than his own personal interest. The lectures the first of which will be given by Professor Harvey Cushing form part of the scheme provided for by a Macewen memorial fund, another object of which is to erect a fitting monument in his memory.

Dr. Malcolm McEarchen, Associate Director of American College of Surgeons, and Dr. Rudolph Matas, New Orleans, Retiring President of American College of Surgeons.

At the evening meeting, October 26th, the program was highly interesting and the papers read came quite up to the lofty expectations raised. The speakers included Professor R. Alessandri, of Rome, Italy; Dr. William J. Mayo, of Rochester, Minn.; W. Sampson Handley, London, England; Dr. L. L. McArthur, Chicago; Dr. John G. MacKenty, New York; Dr. V. P. Blair, St. Louis; and Dr. Robert B. Greenough, Boston. Before giving a résumé of the papers read it will be in place to make a few remarks concerning Professor Alessandri, who was perhaps the outstanding figure and the most arresting personality of the meeting. Dr. Alessandri is a conspicuous figure physically as he is a tall man of magnificent physique. He is also a great surgeon, whose paper was on the whole perhaps the most original contribution to the literature of the meeting. Dr. Alessandri was the surgeon who was standing by the side of Mussolini when the Duce was shot last year by the Hon. Violet Gibson. Professor Alessandri, who as said before is the personal medical attendant of the Fascist leader, not only dressed the wound in the Italian dictator's nose, but had a narrow escape himself. The bullet which injured Mussolini's nose grazed the surgeon's hand. It may be recalled that Mussolini shortly before being shot had delivered an address of welcome to a great congress of surgeons assembled in Rome.

The subject on which Professor Alessandri spoke at the meeting of the Clinical Congress was that of thyroid and parathyroid bone tumors without primary lesion of the thyroid gland.

The point of his address to which especial attention may be directed is that cases have been reported of secondary growths in bones where the lesion was not to be considered either clinically or anatomically as real thyroid neoplasm but where all the characteristics led to simple colloid or hyperplastic goitre. He went on to say, "So many authors have denied the existence of benign metastasizing goitres and have held that the presence of metastasis is a sure proof of the malignancy of the primary tumor. Surely most of the referred cases are of this type, but in my opinion it is not possible to explain in this way every case and I think that the question is not yet solved. There are indeed cases where no change in the thyroid gland is present. In these the exclusive

Royal Victoria Hospital, Montreal

explanation of a steady reference to a malignant primary tumor of the thyroid gland cannot be accepted naturally if we can also exclude a tumor in accessory thyroids." The speaker showed on the screen cases on which he had operated and which came within this category. He therefore deduced that it must be admitted that bone tumors of thyroid or parathyroid type can be found without any primary lesion of the normal thyroid gland or of an accessory one.

Dr. William J. Mayo then gave an address on the cancer problem. Dr. Mayo is a model to be followed by all speakers on medical or surgical questions. He is open minded, concise, coherent and logical. In this address he marshalled in clear sequence all the salient facts of the cancer problem and confessed that ignorance as to the cause of malignant disease is almost as dense as ever. He thought that a foreign organism as the cause of cancer had not been convincingly demonstrated. Dr. Mayo discussed the subject from the biochemical aspect and said, as Adami also said, that efforts directed to its prevention were the most important phase of the problem. Estimating that ten per cent. of the deaths of persons in middle and later life were due to cancer why had not the other ninety per cent. of the population at similar age periods developed the disease? Was freedom due to accident, or did those who escaped the disease possess superior immunity to its cause or causes?

Science had been able to develop soil changes in smallpox, diphtheria, and tetanus. Why not in cancer? Because of natural immunity to the disease only a small proportion of the total population were susceptible to scarlet fever. With Dick's serum the degree of natural immunity of the individual to scarlet fever could be determined, and if it was not sufficient to protect from the disease, it could be increased to normal by serum. Why not in cancer? The development of carcinoma as well as its degree of malignancy might be attributable to the diminished activity of immunizing processes rather than to the nature of the activating agent.

Mr. W. Sampson Handley, of London, England, in discussing the progress in the treatment of breast cancer declared that in the majority of cases the patient could be cured. Operations in his hands had been successful in eighty-nine per cent. of cases and of these forty-five per cent. had remained well at the end of a three to six year period. The speaker showed on the screen his mode of using radium in the treatment of breast cancer and the positions in which the radium tubes should be placed in relation to the growth. He concluded by expressing the belief that as cases were brought under treatment earlier in their development, the prophylactic treatment of breast cancer by means of radium would become more generally successful.

Dr. Vilray P. Blair, of St. Louis, gave an address on cancer of the jaws treated by radium, diathermy and cautery. His motto in the treatment of cancer is that it must be treated like a skunk, either killed or left alone. "Forget the jaw and remember the cancer" was another of his slogans.

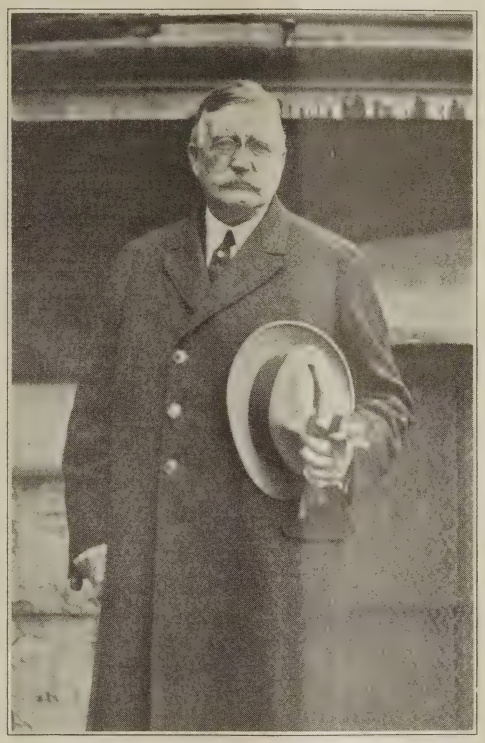
Dr. Lewis L. McArthur, of Chicago, dealing with cancer of the tongue, made some very timely warnings. He urged physicians and dentists to obtain at once competent investigation of tongue sores, which in a number of cases might be found to house cancer, and made a strong appeal to the public in general to take to heart the pleas made for early diagnosis in all cases. He stated that in his own experience seventy-six cases of cancer had been overlooked, sixty-seven of them by physicians and the remaining nine by dentists. He insisted on the advantages of early treatment, pointing out that within the first

thirty days at any rate the infection seemed to be localized.

Dr. John E. MacKenty, of New York, advocated the use of surgery in the treatment of cancer of the larynx coupled with early diagnosis. He explained at length the differential diagnosis of cancer of the larynx and drove home his verbal descriptions by lantern slides illustrating the differences in throat growths between cancer cases and other conditions which resembled them somewhat closely. He declared that when we have the public educated to recognize chronic hoarseness as a danger signal we shall have made progress. He held that radium had failed in the treatment of throat cancer in ninety-six per cent. of the cases and he proceeded to say that it was time that more of the truth about radium was told. Dr. MacKenty showed lantern slides of an artificial larynx he had invented, to be used in cases of total removal of the larynx.

Dr. Robert B. Greenough, of Boston, read a summary report of the Committee on the Treatment of Malignant Diseases with Radium and X Ray. He said that this report showed as good results as the former report going to prove that this means of treatment was standing well the test of time.

On the evening of October 27th Dr. Evarts A. Graham, of St. Louis, described the method devised by him for detecting lesions in the gallbladder. Dr. Graham's method is now known and employed in all parts of the world. He read a paper on the subject at the last meeting of the British Medical Association. It is largely based upon the introduction of a certain dye into the blood which was at once secreted by the liver and thence found its way to the gallbladder and making that organ very plainly visible by means of x ray photographs. This method had proved so successful in the diagnosis of gallstones that subsequent operations were said to have been successful in ninety-eight per cent. of the cases.



Dr. George D. Stewart, New York, president-elect of the Congress

Skin grafting and plastic surgery were the next subjects for consideration. The papers read were devoted mainly to details of lesions and sutures and were rendered more easily intelligible by a large number of illustrative photographs showing conditions before and after treatment. In discussing plastic surgery of the face Dr. Gordon B. New, of Rochester, Minn., pointed out that the cosmetic as well as the functional results must be considered. He insisted that while there were certain definite purely cosmetic operations justifiable there should be a clear understanding between surgeon and patient as to just what was to be done.

In discussing Dr. New's paper, Dr. Fulton Risdon, of Toronto, spoke in glowing terms of the work that had been done during the past ten years in this direction to attempt to make individuals fit to face the battle of life socially and physically. He pointed out that great strides had been made in plastic surgery during the war, but that, unfortunately, much of the wonderful grafting achieved then had proved unsatisfactory, and that considerable changes had been made in the methods used. Dr. New and other surgeons who had conducted research along this line had been doing work which was of great value to mankind.

At the same session Dr. John Staige Davis, of Baltimore, read a paper on transplantation of skin; Dr. Sumner L. Roch and Dr. Allen B. Kanavel, of Chicago, one on Dupuytren's contracture; Dr. Arthur Steindler, Iowa City, one on restoration of function by orthopedic operation; Dr. Henry H. M. Lyle, of New York, one on prevention of loss of function in the hand by the early use of skin plastics, and Dr. Sterling Bunnell, of San Francisco, one on restoration of tendons and nerves.

On Thursday morning in the Windsor Hotel clinical demonstrations were held on the surgery of the ear, nose and throat. Among the most interesting subjects dealt with in this section, because it is the newest, was that of the injection of lipoidol in the diagnosis of pulmonary lesions.

Dr. Samuel Iglauer, of Cincinnati, read the paper and it was discussed by Dr. David Ballon and Dr. G. E. Hodge, of Montreal. Of the clinical demonstrations given that of the use of lipoidol in the diagnosis of pulmonary lesions, as said before, was of the greatest interest because of the comparative novelty of the mode of employing lipoidol for this purpose. Dr. David Ballon, of Montreal, is the pioneer in using bronchoscopic injections of lipoidol which in conjunction with x ray give direct vision in contradistinction to the other methods of employing the substance for diagnosis of pulmonary conditions. Dr. Archibald, chief surgeon to the Royal Victoria Hospital, Montreal, and professor of surgery at McGill University, was one of the first to perform radical operations for the relief of certain pulmonary conditions and he has found that diagnosis of obscure lung lesions are rendered easier and more certain by far by employing the bronchoscopic method of injecting lipoidol followed by x ray examination. In some cases certain lung conditions are said to be impossible of detection except by this method. On Tuesday morning at the section of general surgery, gynecology, obstetrics, urology and orthopedics, Dr. Edward Archibald and Dr. David Ballon gave a demonstration of lung mapping by injection of lipoidol in the

diagnosis of pulmonary conditions. At the Pathological Institute of the Royal Victoria Hospital Dr. David Ballon gave two demonstrations on the use of lipoidol in pulmonary diagnosis by the bronchoscopic method, the first of these was a lantern demonstration and the second a demonstration on a living subject.

On the evening of October 28th Professor John M. C. Fraser, of Edinburgh, gave an address on the involuntary nervous system in relation to abdominal disease and Professor L. E. Barnett, of Dunedin, New Zealand, one on recent advances in our knowledge of hydatid disease. These addresses were followed by a symposium on sterility in men and women in which Dr. Edward L. Keyes, of New York; Dr. Robert I. Frank, of New York, and Dr. John Osborn Polak, of Brooklyn, took part.

At the afternoon session on October 29th, at the meeting of the Section on General Surgery, Gynecology, Obstetrics, Urology and Orthopedics, a fracture symposium was held, the chairman of which was Dr. Charles Scudder, of Boston. Dr. Nathaniel Allison, of Boston, dealt with the keeping of records and the securing of results in fracture cases. Dr. Joseph A. Blake, of New York, dealt with the principles of fracture treatment. Dr. Robert S. Osgood, of Boston, spoke on compression fracture of the spine. Dr. Kellogg Speed, of Chicago, with the treatment of the common fractures of the carpus. Dr. Paul U. Magunson, of Chicago, with the treatment of certain fractures of both bones of the forearm. Dr. Frederick J. Cotton, of Boston, with the reduction and artificial impaction of fractures of the neck of the femur. Dr. William O'Neill Sherman, of Pittsburgh, with fracture of the shaft of the femur, its treatment and results. Dr. Astley P. C. Ashhurst, of Philadelphia, with the same condition. Dr. Oscar F. Mercier, of the Notre Dame Hospital, dealt with temporary metallic osteosynthesis in the treatment of fractures, technic and instrumentation. Dr. C. B. Keenan, of Montreal, on recognition of dislocation of the os calcis in fracture of this bone.

Dr. Fred J. Tees and assistants, Montreal, gave a practical demonstration of application of Thomas splint.

The evening of October 29th was convocation evening, when the Fellowship of the College was bestowed upon 470 practitioners drawn from eight different lands. It was an impressive spectacle. The front half of the hall was given up to the 470 newly admitted Fellows who, arrayed in their black and scarlet Fellowship gowns, their heads covered by black mortar boards with scarlet tassels, trooped in. One was struck with the vigorous physical aspects of the men, some indeed were giants in stature and build, with few exceptions, while all appeared fine specimens of manhood. It is probable that in no civilized country would be found a like number of men of more imposing physical appearance. The proceedings opened promptly at eight p. m., when the officers, regents and guests of honor marched to the accompaniment of martial music, headed by the army officer bearing the great mace through the packed hall to the platform. The British National Anthem was then played after which the very Reverend Arthur Charles Carlisle, Dean of Montreal, delivered the invocation.

Honorary Fellowships were then conferred on Professor R. Alessandri, of Rome; Dr. Archibald Young, of Glasgow; Mr. W. Sampson Handley, London, England; Sir Ewen Maclean, Cardiff, Wales; Professor L. G. Barnett, Dunedin, New Zealand; Professor John Fraser, Edinburgh, Scotland; and Professor G. D. Wilkie, Edinburgh, Scotland, each of these was introduced individually by a member of the Board of Regents of the College who proclaimed the titles, degrees, qualifications of the person thus honored. Next followed the presentation by Dr. Franklin H. Martin, Director General of the College of the 470 candidates for admission to the Fellowship. Four hundred and forty-four of these were from the United States, eighteen from Canada, one from Brazil, one from Cuba, three from Guatemala, one from China, one from Korea and one from New Zealand. After the ritual of admission was over, Sir Ewen J. Maclean delivered the Fellowship Address in the course of which he touched upon the much vexed question of publicity of medical men in the public press. He said that he favored the greatest care in regard to allowing articles regarding medical men or by medical men to get into the daily press. Any sort of article which gave the impression that a particular doctor had a monopoly of up to date knowledge on any particular disease or organ was highly reprehensible. On the other hand, to forbid a medical man to accept positions of usefulness on public bodies, on account of the publicity such positions brought to the holder, was an objectionable exaggeration, and contrary to the best spirit of the profession.

Dr. W. W. Chipman in his presidential address took as his subject Lord Lister and gave a scholarly and eloquent appreciation of that great man and his deeds for the good of mankind. He pointed out that the bronze doors of the halls of the College of Surgeons in Chicago were ornamented with six panels of six great men of medical history. Below the panel of Pasteur was the panel of Lister, a great man if Quaker origin, who had battled with many obstacles and made modern surgery possible.

Dr. George David Stewart, of New York, is the president elect of the American College of Surgeons for the ensuing year. Dr. Stewart was born in Nova Scotia. In 1889 he was graduated from the Bellevue Hospital Medical College, New York. At the present time he is professor of surgery at the same college. Dr. Truman O. Brophy, of Chicago, and Dr. Frank H. Newburn, of Edmonton, were elected vice presidents for the ensuing year.

Additions to the board of regents for a term of three years were: Drs. Irven Abell, Louisville; Alfred T. Bazin, Montreal; Merritte W. Ireland, Washington; Franklin H. Martin, Chicago and C. Jeff Miller, New Orleans. As said before, this is a somewhat desultory account of a very successful meeting. The hospitals of Montreal cooperated most thoroughly with the College and provided a splendid series of clinics from which no doubt the visitors derived instruction and inspiration. Of course, many happenings of interest have been omitted, but it would be impossible within the scope of a limited article to refer to everything.

It may be mentioned that during the meeting the magnificent Maternity Department of the Royal Victoria Hospital was opened. This building will accommodate about 260 patients, is thoroughly equipped and is a model of its kind. Another occur-

rence which ought to be referred to as it is of great significance was the alliance, so to speak, between the American College of Surgeons and the Moving Picture Producers' and Distributors' Association. Of course, films have been employed in the service of medicine and surgery for some considerable time and have proved of infinite value in depicting and aiding in the explanation of many surgical and medical problems, the details and technic of operations and so on. It is felt that the use of motion picture films may be greatly developed and be of still greater service to humanity and to the medical profession by illustrating operations, some of them, for instance, intricate, performed by masters of surgery. By such means student the world over may study these operations, and learn much from them to the benefit of the whole community. Further future generations will be able to view the great surgeons of the past to their own advantage and to the advantage of their patients.

Mr. Will H. Hays, the head of the motion picture interests, came to Montreal on the last day of the meeting to confer with the Regents of the College and to give an address. His address embodied the remarks made above as to the great value of cooperation between surgeons and physicians and those in control of the motion picture organizations. A special Committee of the College was appointed to develop the broadest possible use of motion picture films in medicine and surgery.

Dr. J. Bentley Squier, of New York, was made chairman of the committee. The other members of the committee are Dr. W. W. Chipman, Montreal, president of the American College of Surgeons; Dr. Franklin H. Martin, its director general; Dr. Allan Craig, Dr. Bowman Crowell and Dr. Malcolm McEachern, Chicago, its associate directors; Dr. Charles H. Mayo, Rochester, Minn., Dr. George W. Crile, Cleveland; and Mr. Will H. Hays, president of the Motion Picture Producers and Distributors of America, Inc.

A feature of the meeting which is well worthy of mention and praise was the really admirable manner in which the daily journals of Montreal and the *Star*, in particular, reported the meetings. The addresses reported as they were reported and interviews given by prominent members of the medical profession as at Montreal during the session of the Congress cannot but have an educative influence for good on the general public.

News Items.

New Course in Medical Biology.—The Michigan State College is offering a full college course for the training of laboratory experts, bacteriologists, serologists, chemists and pathologists, to be administered by a committee of the college faculty, with Dr. Ward Giltner, professor of bacteriology and hygiene, as chairman. Correspondence for information should be addressed to Dr. Giltner.

Tuberculosis Prevention Society.—The new dormitory at Point Pleasant, N. J., of the Society for the Prevention of Tuberculosis Among Children was formally opened on October 11. Among the speakers were Dr. Cepulic Vlad of Sagrad, Jugoslavia, Dr. Lydia Kemper of Berlin, Dr. A. F. Hulse of New York, Dr. M. J. Fine of Newark, N. J., and Mrs. Quimby, superintendent of the Preventorium; Dr. Reselin of Glasgow, and Dr. Stojanargilz.

X Ray and Surgical Clinic at French Hospital.—Announcement has been made by the French Hospital, New York City, that a combined x ray and surgical clinic will be held on Tuesday mornings, which physicians are invited to attend.

Foreign Health Workers Studying Here.—Among foreign health workers studying health conditions and methods in the United States are the following, under a grant from the International Health Board: Dr. Titu Gané, inspector general in Transylvania and professor of medicine at the University of Cluj, Rumania; Dr. Marius Kaiser, head of the Division of Infectious Disease Control, Central Health Service, Austria; Dr. Wilfred A. Nicholas, former port health officer of Singapore. After some weeks of observation at the New York State Department of Health, Dr. Nicholas will go to the Johns Hopkins School of Public Health for a two years' course.

Gifts and Bequests.—Dr. Robert Grigg Reese, whose death occurred in New York City on October 18, bequeathed to the New York Eye and Ear Infirmary, a share of his estate, the value of which is not known at this time, to be used for the erection and maintenance of a glaucoma pavilion to be known as the Reese Pavilion. Dr. Reese left his residence at 50 East Fifty-second Street, together with his medical practice, to his nephew, Dr. Algernon B. Reese, with certain provisions.

Mrs. Elizabeth Clark Rogers, who was killed in a fall or leap from the sixteenth floor of the Hotel Commodore, New York City, on November 2, bequeathed approximately $300,000 to the Medical School of Harvard University. Among other bequests is a $50,000 trust fund for the Niagara Falls Memorial Hospital in memory of her father, the late Dr. Gardner C. Clark of Niagara Falls.

Through its report for 1925, the New York Academy of Medicine calls attention to the following extract from the will of Mrs. Celine B. Hosack: "I do give and bequeath unto my executors, hereinafter named, the sum of ten thousand dollars, in trust, to apply and pay the same (or so much thereof as may be necessary) to the Roosevelt Hospital in the City of New York, to purchase a bed, which, in memory of my husband, shall be known as the Hosack Bed, and which shall be occupied from time to time by such sick and needy physicians as may for that purpose be named or designated by the President and Treasurer for the time being of the New York Academy of Medicine."

A second gift of $25,000 to the Lutheran Hospital of Manhattan has been made anonymously in memory of the late Oscar Scherer, pioneer leather manufacturer, who died in 1923.

Death of Dr. Sartorius.—Dr. August Matern Sartorius, president of the laboratories of Reed & Carnrick, Jersey City, died at the New York Post-Graduate Hospital, November 2, 1926, after an illness of five weeks. Dr. Sartorius was graduated in 1909 from the Brooklyn Polytechnic Institute, where he specialized in science, and received his medical degree from Yale University in 1912. In 1913 he became associated with the laboratories of Reed & Carnrick, where he began to institute research for pluriglandular products, in which he had already achieved unusual success at the time of his death. This is believed to have been due to pathological conditions traceable to an unusually severe experience in the front line trenches when Dr. Sartorius was serving in France as an officer in the Medical Corps of the Army.

Medical Moving Pictures Endorsed by American Surgeons.—At a recent meeting in Montreal, the American College of Surgeons sponsored the use of moving pictures in medicine and surgery. A special committee made a report on the subject, which was adopted. The members of this committee are, chairman, Dr. J. Bentley Squier of New York City; Dr. W. W. Chipman of Montreal, president of the American College of Surgeons; Dr. Franklin Martion of Chicago, director general of the college; Dr. C. H. Mayo of Rochester, Minn.; Dr. Allen Craig of Chicago; Dr. George W. Crile of Cleveland; and Dr. Bowman Crowell and Dr. Malcolm MacEachern, directors of the college. The committee suggested that a bureau of information be established at the headquarters of the College of Surgeons in Chicago to make available to the medical profession information as to what films are available for both lay and professional use, where such films can be obtained, and whether they are reliable and satisfactory for teaching purposes.

Testimonial Dinner to Dr. Downing.—A testimonial dinner to the Deputy Commissioner of the State Department of Education, Dr. Augustus S. Downing, was held at the Hotel Commodore, New York, December 9, 1926, at 7:30 p. m. The presiding officer was Dr. Livingston Farrand, president of Cornell University, and the principal speaker of the evening was Dr. Nicholas Murray Butler, president of Columbia University, and Dr. Wendell C. Phillips, president of the American Medical Association.

Personal.—Dr. Adolf Lorenz of Vienna arrived in New York on November 21st to resume his work throughout the country.

Dr. Francis Weed Peabody of Boston has been made a member of the Board of Scientific Directors of the Rockefeller Institute for Medical Research. Dr. Peabody is professor of medicine at the Harvard Medical School and Director of the Thorndike Memorial Laboratory in Boston City Hospital. He is a graduate of Harvard University and of Harvard Medical School and was a Fellow of Johns Hopkins Medical School. He is a trustee of the China Medical Board of the Rockefeller Foundation.

Effie J. Taylor, a member of the faculty of the Yale School of Nursing, has been appointed professor of psychiatric nursing at Yale University. Miss Taylor was director of the Army School of Nursing during the World War, and was for seven years director of the nursing service at the Henry Phipps Psychiatric Clinic at Johns Hopkins.

Dr. Nathan Raw of London, internationally known authority on public health, has recently been visiting New York City. Dr. Raw was one of the speakers at the fourth annual Sickness Prevention in Industry Conference, called by the Brooklyn Tuberculosis and Health Association of the Bureau of Charities, and held at the Grand Central Palace, New York City.

Dr. Adolph G. G. de Sanctis has been appointed professor of pediatrics at the New York Postgraduate Medical School and Hospital.

Society News and Notes.

The Medical Society of the County of New York held its 121st annual meeting recently, at which the following were elected officers for the coming year: president, Dr. Henry S. Patterson; first vice-president, Dr. John Douglas; second vice-president, Dr. Dewitt Stetten; secretary, Dr. Daniel S. Dougherty; assistant secretary, Dr. J. Milton Mabbott; treasurer, Dr. James Pedersen; assistant treasurer, Dr. Ten Eyck Elmendorf; censors, Dr. Edward M. Colie, Jr., Dr. Terry M. Townsend, Dr. Howard G. Meyers; chairman of the Committee on Membership, Dr. Percy H. Williams; chairman of the Committee on Civil Policy, Dr. Charles G. Heyd; chairman of the Committee on Legislation, Dr. Walter T. Danreuther; delegates to the Medical Society of the State of New York, Dr. Milton A. Bridges, Dr. Coley, Dr. Elmendorf, Dr. William P. Healy, Dr. Mabbott, Dr. Patterson, Dr. Pedersen, Dr. Malcolm C. Ross, Dr. Mary D. Rose, and Mr. Townsend.

* * *

Under the auspices of the Lutheran Hospital Association, a ceremony was conducted on Sunday, November 28th, for the breaking of ground preparatory to building the new Brooklyn Lutheran Hospital at East New York Avenue and Junius Street. D. Tietjen, president of the association; A. H. Legenhausen, chairman of the Board of Trustees; and Dr. Vincent Barber, president of the Lutheran Hospital staff, officiated at the ceremony. There were addresses by a number of prominent clergymen of Greater New York.

* * *

The New England Industrial Nursing Association held a meeting in Boston on October 9, at which the chief speaker was Joseph A. Parkes of the Industrial Accident Board of Massachusetts. The discussion centered on injury to workmen and compensation.

* * *

Coming December meetings include the American Association for the Advancement of Science, Philadelphia, December 27-January 1; the National Community Center Association, St. Louis, December 28-31; the New York Microscopical Society, Friday, December 17, at the American Museum of Natural History; and the annual meeting and dinner of the New York Academy of Sciences, Monday, December 20, at the Hotel Biltmore, New York City. Upon the last occasion, President Henry E. Crampton and Dr. G. Kingsley Noble will make addresses. Some interesting motion pictures will be shown.

* * *

At the stated meeting on December 2, of the New York Academy of Medicine, the following were elected officers for the coming year: president, Dr. Samuel Lambert; vice-president, Dr. William H. Park; treasurer, Dr. Seth M. Milliken; trustees, Dr. Charles L. Dana and Dr. Samuel A. Brown; member of the Library Committee, Dr. Eugene F. Dubois; and member of the Committee on Admissions, Dr. Alexis Moschowitz. The selection comprised the entire slate of regular nominees, who were elected by a unanimous vote.

* * *

The American Society of Medical History held its ninth meeting on November 25, at the editorial offices of *Medical Life,* New York City. Dr. C. Hemmeter, of Baltimore, spoke on the Philosophy of History. Dr. Louis Faugères Bishop presided at the meeting.

* * *

The National Committee for the Prevention of Blindness held its twelfth annual conference, December 1-2, at the Russell Sage Foundation Building, New York City. The program included joint meetings with the American Social Hygiene Association, the National Organization for Public Nursing, and the Eastern Association of Indian Affairs. There was a sight saving class conference, at which the discussion centered upon a report of the British classes based on a recent study, and a special meeting in commemoration of the late Louisa Lee Schuyler.

* * *

The Sixth Conference of the International Union against Tuberculosis will be held in 1928 at Rome, Italy. One of the chief speakers at the last conference, held in Washington in October, was Prof. Gaetano Ronzoni, of Milan, whose paper was on contagion in tuberculosis among adults.

* * *

Dr. Abr. L. Wolbarst was the guest of the Orange Mountain Medical Society, East Orange, N. J., on Friday, November 19th. He read a paper on "Hematuria, With Special Reference to Diagnosis."

* * *

The New York County Chapter of the American Red Cross has recently made public a report of its work during the last twelve months. Financial relief to disabled war veterans and their families amounted to more than $40,000. More than 25,000 men, women and children have taken life-saving instruction in connection with the Red Cross life-saving program. Nearly 600,000 surgical dressings for sixteen of the city's hospitals were made by volunteer workers. By means of a process perfected by Red Cross workers, 56 volumes of raised type books for the blind have been duplicated. Volunteers have also made 12,000 original pages of raised type books, which have all been sent to the Library of Congress in Washington for general distribution to the blind. A total of more than 15,000 individuals and families have been aided by the New York Chapter.

* * *

The Baltimore Medical Club of New York City held its autumn meeting at the Hotel Commodore, Lexington Avenue and Forty-second Street, New York, on Wednesday evening, December 8, 1926, at 7.00 p. m. The guests of the evening were Dr. J. M. H. Rowland, dean of the Medical Faculty, University of Maryland, Baltimore, and Dr. Wendell C. Phillips, president of the American Medical Association, who gave addresses on matters of especial interest to Baltimore graduates. There was also an entertainment furnished by popular theatrical stars under the leadership of Mr. Howard Wade Kimsey and Mr. Arthur Gordoni. This club consists of graduates of the medical colleges of Baltimore residing within the metropolitan district, which comprises New Jersey, Connecticut, Long Island and New York State within a radius of sixty miles. The officers are: Dr. David E. Hoag, president; Dr. Dougal Bissell, vice-president; Dr. Dumont Elmendorf, secretary; Dr. W. G. Lough, treasurer; Dr. W. B. Pritchard, chairman of Executive Committee; Dr. L. Winfield Kohn, chairman of Committee on Attendance and Publicity; Dr. J. Morley Hitzrot, chairman of Reception Committee.

Book Reviews

HEART DISEASE

Principles of Diagnosis and Treatment in Heart Affections. Sir James Mackenzie, M.D., and James Orr, M.B., Ch.B. Third edition. London and New York: Oxford University Press, 1926. Pp. 242.

This third edition of Mackenzie's well known small book has been prepared by Dr. James Orr, his associate at the St. Andrew's Institute for Clinical Research. In preparing the present edition the main object has been to make it representative of the newer teaching of Mackenzie, without sacrificing the distinctive clinical character of the original work. Mackenzie's newer theories are expounded in the fourth edition of his large book, which appeared just before his death. They postulate that all symptoms are due to a disturbance in the reflex arc of the regulating mechanism of the organ. Although, to the reviewer, the application of these theories does not always appear to clarify the subject, the book is written with Mackenzie's customary lucidity and force of style.

A number of points are worthy of mention. The author suggests that exhaustion in patients with heart disease is usually due to vasomotor disturbance and not to the heart. This is an important point for the practitioner, for such patients are usually relieved by a tight abdominal binder. The discussion of neurocirculatory asthenia is clear, but undue emphasis is placed on toxemia as a cause for the symptoms, and the constitutional element so important in many cases is neglected. In the chapter on prognosis, the dependence that must be placed on the extent of recovery after appropriate treatment is well stressed. The principles underlying the diagnosis of the cardiac irregularities, affections of the myocardium, as well as the treatment of heart disease, are briefly but adequately expounded. The book will continue to be very valuable to the practitioner as an introduction to the study of cardiac disorders.

CHEMOTHERAPY

The Scientific Basis of Chemotherapy. By Iwan Ostromislensky, Ph.D., M.D. Formerly Director of the Chemotherapeutic Section of the Scientific Institute, Glavchimfarmzaw, Moscow. New York: Published by the Author, 1926. Pp. 142.

The author presents a new dualistic chemotherapeutic theory and gives its relationship to Ehrlich's side chain theory. He compares the mechanism of the curative action of salvarsan preparations, of quinine and of his recently discovered preparation pyridium. There is a chapter on the function of protective colloids in medical preparations, and detailed information as to the nature of pyridium, its chemical and physical properties, its biological constants and its possible therapeutic value.

Pyridium is stated to have a group selective action on the cocci genus, being bactericidal toward streptococci, Micrococcus tetragenus, staphylococci, pneumococci, and diplococci of various strains. It appears to have a high penetrating power. The action of pyridium in the following diseases was investigated: chancroid; diseases of the eye; serpiginous ulcer of the cornea, conjunctivitis, keratitis herpetica; pyorrhea alveolaris; infections of the nose and throat; prophylactic in surgical cases; furunculosis; phlegmona; osteomyelitis; paronychia; cystitis; various gynecological conditions; gonorrhea.

If the original findings of the author and his coworkers are confirmed the remedy may prove to be a valuable addition to the present day list of the therapeutic agents. Its possible value in the treatment of gonorrhea should lead genitourinary specialists to investigate the remedy.

CIRCULATION, NORMAL AND ABNORMAL

The Heart. By Alexander George Gibson, D.M., F.R.C.P. London and New York: Oxford University Press, 1926. Pp. 108.

It is the object of this little book to deal briefly with the fundamental principles which underlie the study of the normal and abnormal circulation, and to illustrate these by their applications in general practice. It is designed for students and practitioners. In the short compass of one hundred duodecimo pages the author has succeeded remarkably well in presenting the important principles and facts necessary for the understanding of the functioning of the normal circulation, as well as of the disturbances in structure and function consequent on disease. Principles of prognosis and treatment are admirably presented. Throughout the book the clinical point of view is predominant. The author's claim not to have omitted any fundamental aspects, be it of craft or of philosophy, which bring meaning into these phenomena of disease, may be freely allowed.

LATENT TUBERCULOSIS

La Tuberculose Pulmonaire Latente—Pretuberculose sommets suspects. Par J. Rieux, Medecin-Inspector, Ancien Professeur au Val de Frace. Paris: Gaston Doin et Cie, Editeurs, 1926. Pp. 247.

This is a highly interesting book on an important subject. Rieux, who has been a military surgeon for thirty-five years, serving throughout the World War, has dedicated this book to his noble comrades, the army physicians of France. He says that he has written the book for the purpose of solving the difficult problem of latent tuberculosis in the endeavor to establish scientifically the basis of a practical method to decide definitely in each particular case whether latent tuberculosis is absent or present. The book comprises six chapters. In the first the author describes the various stages of tuberculosis in the human being, giving Debré's and in addition Bernard and Vitry's interesting statistics of positive tuberculin reaction. In both tables of statistics the highest percentage of positive reaction in children occurs between the ages of thirteen and fifteen. Unfortunately, Rieux does not state whether the cutaneous reactions were obtained by the Von Pirquet or the Mantoux tests, for the latter is known to be far more reliable than the von Pirquet. He maintains that in the female population the greatest tuberculosis mortality is between the ages of twenty and twenty-five. This does not correspond with our own more recent statistics which would show that the mortality is greatest between the ages of fifteen and twenty, and in girls even between twelve and eighteen. The second chapter the author consecrates to the symptoma-

tology of latent tuberculosis and admits the great difficulty in its diagnosis. He pays considerable attention to the family and personal history, and concerning the symptomatology he does not agree with Rist, who believes that positive sputum is sufficient, and necessary even to determine a very early tuberculosis. In the third chapter, which deals with the radiographic pictures of the lung, the author established the following distinct types. First, the normal type, then the hilus types which he subdivides into cicatrized and active; a third is pleural lesions, which he again divides into cicatrized and active; and, lastly, the mixed type in which all the previous pictures may be combined. The fourth chapter treats of biological reaction in which the various and well known tuberculin reactions are described, from von Pirquet down to Wildholz. Rieux wisely admits the abandonment of the ophthalmic reaction. He claims that the Mantoux reaction is rarely resorted to because it is more complicated, but admits that it is a little more sensitive than the von Pirquet. In the fifth chapter he described the pathology and symptomatology of the various types already mentioned. The final chapter, however, the author consecrates exclusively to diagnosis, differential diagnosis and prognosis of latent or occult tuberculosis. Nothing new is offered in these chapters but he reviews carefully all that is known of the diagnosis and differential diagnosis and emphasizes the importance of combining physical signs, symptoms and personal history in arriving at some definite conclusions in strongly suspected cases. He finally urges a guarded prognosis in all cases where a latent tuberculosis is absolutely confirmed by the diagnostic means at our command.

Rieux's studies of latent tuberculosis are made particularly interesting by his giving the radiographic pictures of twelve cases of the various types of tuberculosis and of one normal thorax. As a whole, it can be said that the book is one of the best of its kind and of value to the specialist as well as to the general practitioner.

DERMATOLOGY

Fundamentals of Dermatology. By Alfred Schallek, M.D. Illustrated with Fifty-Four Engravings. Philadelphia and New York: Lea & Febiger, 1926.

The aim of this work is to give the fundamentals of dermatology in a concise and thorough manner, for the particular use of students and general practitioners, replacing a compend which has been in use for some years. The author has succeeded in this aim in a satisfactory degree. This work treats the subject in a manner which places the fundamentals within easy reach of the reader who has not the time nor the wish to wade through the average dermatological textbook. Nothing but the essentials has been incorporated in this work. This is particularly noticeable in the consideration of syphilis, which is admirably treated in less than fourteen pages of reading matter. The author has condensed a vast amount of useful advice in a two page chapter on "Dermatological Aphorisms," a careful study of these aphorisms will be of the utmost practical value both in the diagnosis and treatment of skin lesions. The printing is good and the illustrations excellent. It is to be regretted, however, that some of the latter are not in color.

LEADERSHIP

Leadership. A Manual of Conduct and Administration by William Colby Rucker, M.S., M.D., Dr.P.H., Surgeon, U. S. Public Health Service. New York: The Macmillan Company, 1926. Pp. 171.

Once in a while there comes to the reviewer's desk a book which is easily read and is full of stimulating and well organized ideas. Rucker's book taps a new vein so far as the field of institutional and sanitary medicine are concerned. It is well written and presents in an interesting and stimulating form the basic principles of the art and practice of leadership. The foreword is written by Surgeon General H. S. Cumming of the United States Public Health Service and he expresses the very pregnant thought that "the hospital administrator and the practitioner of public health must be more than a physician and surgeon, an engineer or a technical worker, he must be an administrator and he should understand the principles of leadership as they are applied to the multiform operations in the remediation and prophylaxis of disease."

In the past we have been so busy with the technical details of prophylaxis and cure that few have given thought to those attributes of mind and character which best qualify those who head such movements for leadership of themselves and the general public. *Leadership* lays these down without preaching and in a manner which renders it valuable to those who are engaged in the indoctrination of the public in medical service and public health matters.

While written primarily for the Public Health Service, it is a book which should prove exceedingly useful to all of the medical services, both federal and state. It is well printed and bound and is of convenient size. Its table of contents and its index are full and complete. It should meet with a hearty welcome.

THE DOCTOR LOOKS AT ECCLESIASTICAL ARCHITECTURE

Historic Churches of the World. By Robert B. Ludy, M.D. Boston: The Stratford Company, 1926. Pp. 325.

Wherever we find man there we find places of worship. While the name and the attributes of the duty vary, while the form and dimensions of the place of worship differ widely, from the open air altar of the Aztec to the massive Cathedral of St. Peter's in Rome, there is always some place of worship. We have not really seen England until we have seen St. Paul's and the cathedrals of the East Coast; no visit to Paris is complete without a view of the Madeleine; not to have seen the Parthenon is not to have seen Athens, while the Cathedral *is* Rheims.

Dr. Ludy covers an interesting field in a most interesting manner, giving descriptions and illustrations of hundreds of historic churches in both the old world and the new; from the pre-Christian temples of Egypt and Asia to the early missions of the California padres. Even the simple little meeting houses of the austere Pilgrims are included.

All who are interested in the early history of the United States will find in Dr. Ludy's book a great deal that will interest him concerning the churches of that period.

Medicoliterary Notes.

The report of an interesting set of experiments has been announced as to appear in the near future in *Industrial Psychology*, published by Colgate University. These experiments were conducted during the past year by Donald Laird, professor of psychology at the university, assisted by William Wheeler, Jr., now at the College of Physicians and Surgeons of Columbia University, New York City, and had to do with the physical and mental effects of sleep. The mental reaction of sleep was taken in caloric values. One of the interesting discoveries made was that a good soft bed is equivalent in value to two hours of sleep. It was found that, after eight hours of sleep in a good bed, about six calories of energy were used, as opposed to eleven calories in a hard, uncomforable.

Rip Van Winkle, the nickname given to the armored dinosaur which has recently been placed on exhibition in the London Museum of Natural History, was a vegetarian, according to the label attached by naturalists to its glass case, says the *New York Times*. Thus it has taken thirty million years to explode the myth that the animal was a murderous monster and terror to such men as Mr. Neanderthal and M. Cro-Magnon, the most famous of the prehistoric people. According to the naturalists a tiny disease carrying flea which occupies a case adjoining that of the dinosaur, was a far deadlier creature.

"When the Medical Profession of New York Paid Homage to the Autocrat of the Breakfast Table," is the title of an interesting account in *Notes and Abstracts* for October of the dinner given in honor of Dr. Oliver Wendell Holmes at Delmonico's, then on Fifth Avenue at Fourteenth Street, on April 12, 1883.

* * *

According to a report of the British Railways recently made public, only one passenger lost his life as the result of a railway accident in Great Britain in 1925. This man was not killed outright, but died afterward from shock due to bad health at the time. In the years 1908 and 1901 there was not a single fatality among passengers. The only recent year showing a large number of deaths in railway accidents was 1915, when 224 soldiers were lost in a troop train accident. In 1923 there were 25 deaths, in 1906 there were 53, and in 1913 there were 33. In 1909 there was one fatality, 6 in 1914, and in 1919 and 1916, there were 3 each.

The Jassy Medical Association of Bucharest has announced recently through the press that, after fifteen years of research, Dr. Petrof, a Bessarabian, has succeeded in discovering and coloring exanthematic typhus bacilli. His theory is that the bacillus originates with an ordinary beetle, from which it is transmitted to animals, thence to man. The Jassy association is subjecting Dr. Petrof's work to a thorough examination preparatory to submitting a report to the Paris Institute of Science.

Abstracts from Current Literature

DERMATOLOGY

The Febrile Types of Erythema Multiforme and Erythema Nodosum.—George Blumer (*Boston Medical and Surgical Journal,* September 9, 1926) is inclined to think that there are febrile types of both erythema multiforme and erythema nodosum which are not obviously secondary to preceding infections or intoxications; that there is some evidence of an epidemiological nature which suggests that febrile erythema multiforme and febrile erythema nodosum may be specific infectious diseases, and that there is suggestive evidence that the febrile types of erythema multiforme and erythema nodosum may be manifestations of streptococcus infection. It is possible that the two types, febrile erythema multiforme and febrile erythema nodosum, may both be expressions of the same form of infection, though this cannot be proved until the discovery of the etiological agent or agents is satisfactorily substantiated.

Etiology of Herpes Zoster.—Rufus Cole and Ann G. Kuttner (*Journal of Experimental Medicine,* December, 1925) studied nine cases of herpes zoster, and made inoculations into a series of animals, in an attempt to produce lesions in them by the injection of material obtained from the vesicles and involved skin. These attempts proved unsuccessful in rabbits, guineapigs and monkeys.

Curative Treatment of Vitiligo.—Joseph Rivière (*Urologic and Cutaneous Review,* February, 1926) recommends alternating the actinotherapy both local and general with high frequency effluves and static baths, finally, to act upon the hematopoiesis, the pigment function of which appears to be affiliated with it, and to obtain thus a trophic whiplash cooperating usefully with the functional reequilibrium of the integument. Sometimes it is advantageous to apply x rays to the liver and spleen with a view to exciting the pigment forming organs. It is also equally of advantage to stimulate the hepatointestinal function by means of calomel and cholagogue salicylates. These remedies, since they are alkaline, combat at the same time any constitutional arthritism. If neuroarthritism is predominant one should resort also to d'Arsonvalization.

Lichen Nitidus.—H. W. Barber (*British Journal of Dermatology and Syphilis,* April, 1926) believes that the disease is not so rare as is commonly supposed. The simple form of the eruption, which consists of minute, discrete papules, is apt to escape the notice both of the patient and the physician, whereas the diffuse, generalized form is often wrongly diagnosed even by professed dermatologists.

The elementary lesion of lichen nitidus is a minute papule formed by a more or less sharply defined granuloma, which lies, as a rule, just below the epidermis. These papules are not usually larger than the head of a pin, flat, conical or globular in shape, and slightly raised above the surface. Their color varies; they are commonly reddish or reddish yellow. A very characteristic feature is that they often have the glistening appearance implied by the epithet "nitidus," and appear as minute reddish spots shining through a transparent overlying epidermis. They are rendered anemic by pressure. There may be no changes in the surrounding skin, having a strictly limited distribution, as on the penis in men, the lower abdomen, groins, and inner surfaces of the thighs, and on the flexor surfaces of the wrists and forearms and backs of the elbows.

In other cases the eruption becomes widespread and loses its primary papular appearance in certain regions. The eruption may consist of diffuse pityriasiform or psoriasiform sheets, which are very characteristic in appearance. Their color varies in different patients and in different situations, being either reddish-yellow, brownish, or reddish-violet. These diffuse sheets may be widespread, but they are particularly likely to involve the joint flexures, such as the antecubital and popliteal spaces. The anterior surface of the wrists and lower part of the forearms, the extensor surfaces of the knees and elbows, the folds of the neck, the submammary region in women, the groins and thighs, the palms and soles and dorsal surfaces of the hands and feet may all be affected. There is both parakeratosis and hyperkeratosis. The nails may also be involved, being brittle and fissured. The buccal mucous membrane may also be involved.

The etiology of lichen nitidus is entirely unknown. The author does not believe the disease to be of tuberculous origin.

Spontaneous disappearance of the lesion has been reported. Fractional doses of x rays have been reported to be of benefit. Crude coal tar paste may also be useful. The internal administration of iodin in the form of a ten per cent. solution in spirit vini rect. is followed by gradual but very definite improvement.

Cryotherapy in Dermatology.—Lorat-Jacob (*Urologic and Cutaneous Review,* April, 1926) employs a cryocautery which measures the pressure exerted and permits intimate contact between the tissues to be treated and the source of the cold. It also obviates one manipulation and economizes the quantity of snow employed by reason of its direct charging.

The cold acts by producing necrosis of the cellular elements at the point of application, producing ischemia and particularly thrombosis, making cryotherapy particularly suitable in the treatment of very vascular tumors. It is also valuable because it leaves inconspicuous cicatrices. It is also indicated in epithelioma of the face of old persons, erythematous or tuberculous pupus, nevi and hyperkeratosis. In xanthelasma of the eyelids cryotherapy is the only local treatment because it is harmless and active. It serves admirably in leucoplasia of the oral mucosa, where it does not expose the epithelium to subsequent degeneration.

Erythema Infectiosum.—A series of seventy-four personally observed cases of erythma infectiosum is presented by Theodore P. Herrick (*American Journal of Diseases of Children,* April, 1926) and all the evidence in these cases indicates that the disease is a distinct entity, is infectious, and results in the establishment of a specific immunity.

The distinguishing features of the disease are its occurrence in epidemics, the lack of constitutional symptoms, the lack of any features distinctive of the other exanthems, the long course and characteristic progression of the rash, its evanescence at all stages, and particularly the irregular but brilliant outlines seen on the arms and legs in the third stage and in the recurrences. The one adult suffering from the disease had no rise of temperature but she felt miserable and her arms ached.

Burns.—E. C. Davidson (*American Journal of Surgery,* 40:5) maintains that the adequate forcing of fluids and the administration of sodium chloride to correct the disturbed metabolic balance are rational procedures in combating the socalled toxemia of burns. Coagulation of the devitalized tissue by the use of tannic acid lessens toxemia. Tannic acid as an initial dressing has an analgesic effect. Secondary infection is limited by this method of treatment because of the absence of a favorable nidus for bacterial growth. Scar tissue formation has been lessened.

Pruritus Ani.—H. B. Stone (*Surgery, Gynecology and Obstetrics,* 42:4) advocates a treatment based upon the principle of the destructive effect of alcohol on nervous structures. It gives prompt and complete relief and there are no serious complications or disadvantages to fear.

The patient is placed in the lithotomy position under light general anesthesia: ethylene gas is particularly suitable, but nitrous oxide or light ether may be employed. Formerly local anesthesia was given in a number of cases, but general narcosis is better. The infiltration of the tissues with local anesthesia dilutes the alcohol and is otherwise confusing by distending the area injected. The field is prepared as for any operation, and by the field is meant the whole of the area involved. At times this may extend backward over the sacrum, forward about the genitalia and groins, and laterally toward the buttocks. The patient can describe the extent of the involvement before operation, but as a rule the inflamed and indurated appearance of the skin itself indicates the region to be injected. The material used is pure ninety-five per cent. grain alcohol without denaturizing substances. This is injected with the ordinary small hypodermic syringes, with fine needles not over an inch long. Larger syringes and coarser needles may lead to placing too much alcohol in one spot or putting it in under too great pressure. The needles are plunged vertically entirely through the skin, and the alcohol injected into the

subcutaneous tissues. Only two to four drops are injected at each puncture. The punctures are spaced about one fourth inch apart and are "stippled" over the entire area involved. The injections are carried up to about one-fourth inch from the anal margin, but are not made within the anal canal itself. The scrotum, labia majora, and folds of the groins have been injected without resulting trouble. Bloodvessels of course are to be avoided when possible.

After completing the injection, the area is sponged off with a wet alcohol sponge. No dressing is used. There is little after soreness, and if the injection has been properly performed, the itching is abolished at once. When the method was first being developed, there was some concern about possible sphincter paralysis, and sloughing of the skin. In no case has there been any muscle disturbance, and with the technic here described, no sloughs of any moment whatever have developed. Among the first cases there were several sloughs, due to the placing of too large a volume of alcohol through single puncture wounds, and also to injecting by mistake into the skin instead of under it. After an injection, there is a noticeable numbness of the perianal skin, but no disturbance of the sensory features of the act of defecation. There is a remarkable return of the skin to normal appearance within a few days after injection.

Rational Management of Skin Grafts.—F. Smith (*Surgery, Gynecology and Obstetrics,* 42:4) says that it is obvious that a graft is parasitic and must exist upon the absorption of "tissue juices" or lymph during its first two or three days of existence. Hence, its intercellular spaces must be open to the circulation of lymph in order that nourishment may be carried to its cellular elements. Whole blood cannot accomplish this requirement and its collection beneath a graft causes it to perish. These considerations make it obvious that the commonly accepted advice to allow for contraction and to cut the graft one-third to one-half larger than the area to be covered is one of the commonest sources of failure. The graft must be cut accurately to size and maintained at normal tension. For the same reason, it must be accurately approximated by carefully placed sutures.

The skin must be free from fat and the graft must be accurately approximated to its base by a proper, even pressure. The proper pressure must be that pressure which insures maximum nourishment, lymph, to the part and the graft and prevents fluid collection, with consequent flap separation. Any factor which will raise the capillary pressure will favor the increased flow of lymph. Further, we know that the peripheral venous pressure varies from five to fifteen millimetres of mercury and that the arteriole pressure ranges from forty to fifty millimetres of mercury. A pressure, then, which will compress the venules, that is, more than fifteen millimetres of mercury, and will partially compress the arterioles, meets our requirement. A dressing at a pressure of thirty millimetres of mercury has been very satisfactory in our experience.

Finally the grafted part should be immobilized for several days. During the first twenty-four hours the graft is glued to its base by coagulated lymph which must not be disturbed.

Succulence and Adherence of the Skin as a Sequela of a Lymphatic Stasis in Processes in the Region of the Parietal Pleura.—Josef Sorgo (*Wiener klinische Wochenschrift,* April 22, 1926) reports upon his observation of an increased succulence and adherence of the skin of the chest in chronic affections of the pleura. This finding is particularly valuable in the diagnosis and proper interpretation of apical processes and, together with röntgenography of the pulmonary and pleural processes, offers a certain differential sign between them. The author has found that a majority of the cases, which are practically diagnosed as apicitis show only changes at the apical pleura with complete röntgenological integrity of the apical pulmonary tissue, and consequently good röntgenograms should be associated also with fluoroscopy. It is still uncertain whether these changes originate primarily in the periosteal or visceral pleura, but this is shown well by a characteristic picture.

There is unilateral or bilateral succulence of the skin fold in the supraspinous fossa or beyond it, with slight dulness in the corresponding area, which is usually considered to be due to the soft parts in the absence of a thickened apical pleural induration, very superficial and peculiar fine and coarser râles which are definitely of pleural origin, but which can easily be mistaken for bronchitic râles and röntgenologically show nothing or uniform clouding of the apical area without local shadows or more or less distinctly pronounced thickenings of the pleura, or the socalled lamellar pleuritis of the röntgenologist. The often very marked pleural changes passing beyond the region of the apex, recognizable by the succulence of the skin fold, with such röntgenological findings allows one to draw the certain conclusion that the frequently reported annually recurring socalled apical catarrhs are nothing else than a progressive advance of the pleural process, which may become very extensive.

With the aid of this skin symptom we are in a position to recognize the pleural changes with great certainty in its initial stages and, particularly to follow the extension with great accuracy, as the succulent skin represents a true projection picture of the changes going on in the parietal pleura. The skin changes described are produced only by pathological processes in the lymphatic area of the parietal pleura, primary or secondary.

The Neurological and Endocrinological Aspects of Ichthyosis, Chronic Indurative Eczema, and Some of the Minor Forms of Socalled Trophic Changes in Dermal Tissues.—The skin and its appendages, including the nails, hair, and pigment bodies, the pilomotor muscles, and the sweat glands, as well as the subcutaneous tissue and the bones, F. M. Pottenger says (*Endocrinology,* March-April, 1926, vol. 10, page 105) are all under the control of the vegetative nervous system. Likewise the relationship is very close between this system and the endocrine glands. The explanation of many pathological changes in the skin structures, accordingly, he is inclined to find in endocrine disturbances, particularly of thyroid secretion. In treating pulmonary tuberculosis he has several times encountered ichthyosis or chronic eczema of long standing which improved greatly on thyroid extract accompanied by intravenous injection of calcium chloride, the tuberculosis also undergoing a parallel improvement. Several very interesting cases are cited. Indicative of the intimate part played by the nerves in these is the fact that all the various mechanisms—trophic, sweat, vasomotor, pilomotor—were affected, and even the subcutaneous fat distribution. Relapses occurred during periods of nervous stress and when the weather grew cold. Since the former are times when nerve imbalance is accentuated and the latter when thyroid deficiency shows most markedly and the calcium content of the cells is relatively low, the author thinks it justifiable to assume that these lesions do not represent a pathologic condition of one phase of vegetative control to the exclusion of others, but rather a general disturbance of all—the nerves, the endocrine organs, particularly the thyroid, and the automaticity of the cell itself, especially as it depends upon its ionic content, its permeability, and its reactivity.

Herpes Zoster Oticus and Allied Conditions.—Thomas Guthrie (*Lancet,* April 3, 1926) reports three cases of this rare condition. It is met within about one in twenty thousand cases of ear disease. Pain about the pinna and mastoid region may be severe and may be present for two or three days before the eruption appears. It may be the first symptoms or be preceded by vertigo. It is sometimes present also in the distribution of the upper cervical and the fifth nerves, due to coincident inflammation of the corresponding ganglia, or in the case of the fifth nerve to its connection with the geniculate ganglion through the great and small superficial petrosal nerves.

As the eruption affects the tympanic membrane and skin of the meatus as well as the pinna, there may be, two or three days after it has appeared, much inflammatory swelling of the meatal walls with otorrhea and sometimes secondary swelling of the mastoid lymphatic gland. These appearances, together with the intense pain, deafness, facial palsy, and sometimes pyrexia, are very suggestive of acute otitis media with mastoiditis, for which cases of herpes zoster oticus are occasionally mistaken. Points of importance in the diagnosis are: 1, the nature and the distribution of the eruption; 2, the type of the deafness, namely, inner and not middle ear deafness; 3, loss of taste, in the corresponding side of the tongue, owing to affection of the chorda tympani nerve; 4, absence of perforation of the tympanic membrane, although its appearance may be much altered by the eruption, and, in any case, an intact drum does not of course exclude disease of the middle ear.

The duration of the disease varies considerably. Some

degree of neuralgic pain usually persists for two or three weeks. The facial paralysis may be evanescent, lasting only a few days, or it may disappear gradually during the course of some weeks. The same applies to the deafness and other symptoms of eighth nerve involvement. In rare cases some degree of facial palsy and nerve deafness is permanent.

Treatment consists of sedatives for the pain, the usual local applications for the herpetic eruption, and massage and electrical treatment for the paralysis if this persists.

Pruritus Ani.—J. F. Montague (*International Journal of Medicine and Surgery*, 39:2) urges that this problem be considered primarily one of diagnosis and secondarily one of therapeutics. The first step in diagnosis is to examine the region locally for evidence of traumatic conditions which may result from abrasion, avulsion, maceration or compression. In addition to traumatic causes however, there may also be infective causes of a bacterial or parasitic nature, and these latter will generally be found to be the causes of direct pruritus. Investigation cannot cease however with the terminal three quarters of an inch of the anal canal, for certain conditions above this area or in neighboring organs are likewise capable of inducing pruritus indirectly. Thus the author reports one case in which examination revealed an ovarian cyst, upon removal of which the pruritus disappeared without any local treatment; another in which overdistention of the seminal vesicles was found to be the cause of the itching; and a third in which the pruritus proved itself a symptom of a carcinoma of the sigmoid colon. Local treatment of pruritus therefore is usually without results, and tragically so in cancer cases.

With the diagnosis of causative factors made therapeutics become a relatively easy matter, since there are happily at our disposal tried and proven therapeutic material and methods. Thus, if traumatic factors are at work, we apply protective ointments or mild antiseptic lotions combined with the use of pruritus vaccine in cases showing a low-grade infection of the skin. If extensive fibrotic changes have occurred, our undercutting operations will be found of value. In the presence of pathological conditions such as condyloma, these must of course be dealt with.

Finally, in cases due to visceral disease we are confronted with the duty of treating the cause as well as the symptom. In every case we should know the causative factors. Just as in the case of a general physical examination we urgently insist upon the importance of a rectal examination so now I insist with equal emphasis on the importance of a general physical examination in every case of pruritus ani, vulvæ and scroti.

Etiology and Treatment of Infantile Eczema.— A. M. H. Gray (*British Journal of Dermatology and Syphilis*, April, 1926) confines his remarks to the facial eczema of infants, and he divides them into three types: 1, Those which commence on the cheeks or forehead, the primary facial type; 2, those which begin on the scalp, and 3, those which occur in association with a general eczema starting somewhere other than on the face or scalp, as in the napkin region.

The primary facial type usually commences as an itchy patch on the cheeks, less commonly on the forehead. The earliest lesions appear to be of an urticarial or erythematous nature. The rash, when established, varies somewhat in distribution and character in different cases and friction appears to play an important part in its production. Itching is intense and spasmodic. Most of the infants are breastfed, and are fat and healthy looking.

The second type shows scurfy patches on the scalp, in the early stages in ring form, later as dark greasy crusts, which when rubbed or scratched lead to an inflammatory reaction.

The third type presents a similar condition, but here the eruption usually begins at a farther distance from the face, and the facial eruption forms part of a general eczematization.

In the primary facial cases there appears to be some specialized form of hypersensitiveness which is not present in the other types, in which there is simply that form of acquired hypersensitiveness which occurs in adult types of eczema. Most of the scalp cases are of an infective type, generally referred to as seborrheic. Facial eczema of infancy and asthma are frequently associated with neurodermatitis. Hay fever and cyclic vomiting are also found, suggesting some underlying diathesis, which often continues throughout life. There is no specific hypersensitiveness to food substance in facial eczema of infants, but these children, like other sufferers from eczema, are prone to give positive cutireactions to various proteins. The occurrence of the acute exudative type of eczematous inflammations of the skin is such a frequent association with an indigestion of fats and sugar that it indicates that the process in the skin and the process in the digestive tract probably have some etiological relationship. Contrariwise, the fact that the majority of infants presenting the same symptoms of indigestion described above do not likewise present a cutaneous reaction points to the inevitable conclusion that some underlying condition, probably systematic, which the eczematous infants possess, is lacking in the noneczematous individuals. A large number of these cases show symptoms of overfeeding, and they improve remarkably when the quantity of food is reduced. The indigestion may cause flushing and some itching of the face, and this may be the reason why the child starts rubbing its face. In the presence of the socalled exudative diathesis, this friction is sufficient to initiate the whole train of symptoms which are included in the primary facial type of this disease.

The treatment is concerned with stopping the friction, partly by restraint. Changes of temperature are avoided by keeping the child in an equable temperature and occlusive dressings. In nonseptic cases zinc paste is valuable; in septic cases starch and boric acid or flavine poultices are helpful. Crude coaltar is good in nonseptic cases. The only dietetic treatment is reduction of the food. Drugs are of little help. In the early scalp cases sulphur and salicylic acid ointment.

NEUROPSYCHIATRY

Hyoscine in Postencephalitis Lethargica: With Special Reference to Its Influence on Carbohydrate Metabolism.—P. K. McCowan, J. S. Harris and S. A. Mann (*British Medical Journal*, May 1, 1926) have found that hyoscine is of undoubted value in the Parkinsonism following encephalitis lethargica. This value is objectively demonstrated by its effect on the blood sugar curve, which is made to approximate to the normal type. This improvement is due to a specific action of the drug, though suggestion may be a subsidiary factor. This action of hyoscine is only temporary, but the prolonged use of the drug does not lead to tolerance or any deleterious effects. The hysterical element in this disease is probably due to lesion of the basal ganglia, and it is suggested that an anomalous lesion may account for similar symptoms in hysteria, chorea, etc. Though in the majority of cases the full benefit of hyoscine can only be obtained by hypodermic administration, there is no doubt that in many cases considerable benefit follows its oral exhibition.

Further Observations Upon Acrodynia.—A. E. Vipond (*British Journal of Children's Diseases*, April-June, 1926) describes the picture of acrodynia as follows:

There is marked photophobia and pain on handling of the limbs. The onset of the disease appears to be a nasal catarrhal condition. The child becomes irritable and cross. A definite rash appears on the body, often an erythema, a papular and even a pustular eruption, all due to a cutaneous irritation. A cold sweat covers the body and limbs (toxemia). The sympathetic system is involved. The hands and feet are cold and the skin presents a bluish red appearance. The interference with the circulation of the extremities is evidenced by bullæ at the tips of the fingers or a superficial gangrene. The locomotor system's involvement is shown by a pseudo-paralysis. Involvement of the sensory system is shown by peripheral neuritis with intense pain in the arms and legs. All the superficial lymph nodes are enlarged, especially in the axillæ and inguinal regions. There is a rapid loss of weight. The optic toxemia produces an intense irritability and the child buries its eyes in the pillow. There is mental irritability and unrest. The reflexes are difficult to obtain. The urine is scanty. The age of the patients is between eight and eighteen months. The duration of the disease is four to sixteen months.

Bacteriologically, the author was able to isolate a diplococcus from the enlarged glands in every case of acrodynia and he used an autogenous vaccine for every patient. Each patient was given 1 c.c. of this vaccine subcutaneously as a primary dose with slight reaction. This was followed by a marked improvement in three days. The author then gave 1.5 to 2:0 c.c. as a dose, and after three to six days more the extremities were nearly normal in color and tem-

perature. After three to four doses more of 4 to 5 c.c. of the vaccine the patients were practically cured in about three weeks' time. The dose of vaccine is rapidly increased until three to five c.c. are given. One c.c of the vaccine contains five hundred million diplococci. The author's success with this treatment has been universal.

Simple Test of Diagnostic Value in General Paresis.—In a series of 180 patients, the cerebrospinal fluid, suffering from various types of mental disorder, was examined, and the result of the acetic anhydride-sulphuric acid test was compared with the Wassermann reaction, the Lange colloidal gold curve, the amount of globulin, and the number of cells. The method of performing the test is as follows:

To 1 c.c. of cerebrospinal fluid in a small glass test tube add 0.3 c.c. of acetic anhydride. Shake the mixture well and then carefully add, drop by drop, 0.8 c.c. of concentrated sulphuric acid. The test tube is then held up against a white background and the presence of a lilac tint indicates a positive reaction; a brown-yellow or a red-yellow is noted if the reaction is a negative one. The lilac color may appear immediately after the addition of the sulphuric acid and disappear in a minute or so. Hence it is important to watch the cerebrospinal fluid as soon as the sulphuric acid is added, or a slightly positive case may be missed. Usually the lilac tint remains for at least five minutes.

The chemistry of this test is not fully understood, but it seems probable that it depends upon the presence of cholesterol in the cerebrospinal fluid.

As a result of these investigations, J. S. Harris (*British Medical Journal,* January 23, 1926) feels justified in drawing the following conclusions:

1. The acetic anhydride sulphuric acid test on the cerebrospinal fluid of cases of general paresis is positive in almost every case (ninety-seven per cent.), and hence is almost as reliable as the Wassermann reaction.

2. It is negative in almost every other type of mental disorder except certain cases of neurosyphilis (other than general paralysis of the insane).

3. It is a test which can be performed with great ease and rapidity and hence is of definite value to the clinician.

Treatment of Pain in Neuralgias.—S. Erben (*Wiener klinische Wochenschrift,* February 11, 1926) selects sciatica as the typical form of neuralgia. Heat applied over the sacral region is indicated in various forms, such as with the thermophore, sandbags, hot air, the Scotch douche, electric light, fango packs, or diathermy. They are all of equal value. In recent cases sweating procedures, such as steam baths, steam cabinets, light baths, followed by rub downs and a stay in a warm room for an hour are of advantage. If these measures do not bring relief within a week or two, stimulating applications to the skin of the sacral region, such as mustard, croton oil and liniments may be tried. Continuous application without blister formation is the ideal procedure. This treatment is continued for four weeks. The quartz light may also be used to induce erythema. Anodynes, such as the various coaltar preparations, may be necessary. If the symptoms are not relieved within four to six weeks, parenteral protein thereby is indicated. One may use the various milk and casein preparations or bacterial vaccines, both of which types of protein therapy act equally well. They should be injected intracutaneously. Infiltration of the area surrounding the nerves with physiological sodium chloride solution has been recommended. Some advise infiltration of the site of exit of the nerves. The patient should stay in bed for two weeks in recent cases. Walking barefoot on cold surfaces must be avoided; also all physical exertion and exposure to dampness.

Blood Sugar Studies in Encephalitis Lethargica.—P. K. McCowan, J. S. Harris and S. A. Mann (*Lancet,* April 17, 1926) found that in postencephalitis lethargica there is a definite derangement of carbohydrate metabolism as shown by the blood sugar curves. The levulose test does not support the contention that there is definite permanent hepatic insufficiency in postencephalitis lethargica. The majority of postencephalitis lethargicas show a hyperglycemia following glucose ingestion, markedly sustained in fifty per cent. of cases. The mental states of depression and stupor were associated with the most pronounced abnormalities of carbohydrate metabolism. No correlation could be found between the clinical pictures and the types of blood sugar curves obtained.

Although no diagnostic value can be placed on blood sugar curves in postencephalitis lethargica, the fact that the only normal curve was obtained in a patient who had recovered from his psychosis suggests that prognostic hyperglycemia found in all the cases is quite in keeping with the suggestion that encephalitis lethargica is of the nature of a toxemia.

Postoperative Psychosis.—G. Brown (*American Journal of Surgery,* 40:4) reports two cases of his own and reviews the literature, concluding that insanity follows a small percentage of operations under anesthesia. An insane heredity is present in some cases; when this is absent there is often a predisposition from toxemia, exhaustion or allied states. The incidence is slightly higher after operations on the genital organs. The sexes are affected in equal proportion. Insanity immediately following operation is due to the anesthetic. Insanity occurring several days after operation is due to the operation itself. Complete recovery usually takes place within three months. Some patients die within a few days and a few never regain normality.

Glossopharyngeal Neuralgia.—A. O. Singleton (*Annals of Surgery,* 83:3) recommends, for its simplicity and comparative ease of performance, the following operative

An incision was made along the anterior border of the sternomastoid muscle from the ear downward for three inches. The sternomastoid retracted outward and the linguofacial vein ligated and cut, and the posterior belly of the digastric isolated. The parotid gland was pulled forward. The stylohyoid muscle with the posterior belly of digastric were retracted downward and backward. The external carotid artery was seen behind and above these muscles, and it was pushed backward. The stylopharyngeus muscle was seen deep beneath the angle of the jaw and above the retracted stylohyoid muscle. Along the lower and anterior border of the stylopharyngeus the glossopharyngeal nerve was seen like a white thread. It was grasped and evulsed. The wound closed without drainage.

A Diagnostic Sign in the Early Ataxic Stage of Tabes.—J. Allison Hodges (*Virginia Medical Monthly,* April, 1926) describes the "stairs sign," which determines the patient's ability to descend properly a series of stair-steps, with the eyes open, but not directed to his feet, or in certain cases with the eyes closed, as one of the most delicate and definite tests of ataxia, often apparent before any other signs. The procedure tests at one time the afferent impressions from both the muscles and joints, deficiency of which is at the bottom of the ataxia of tabes. A short staircase is selected and the patient made to descend the stairs, abstracting his attention from everything else and looking straight before him. If the ataxia is advanced to any degree he cannot lift up his legs and put them down properly in descending, say, eight to twelve steps as easily as he could walk on a floor. If it is a case that does not manifest ataxia with the eyes open, the patient is made to close his eyes and descend a smaller number of steps; ataxia will then often be manifested to an unexpected extent. Nine out of twenty-three cases of early tabes showed ataxia by this test before it was demonstrable by other signs or before other positive tabetic reflexes and manifestations became apparent.

Phases of Neurosyphilis.—Abraham Myerson and Morris Yorshis (*American Journal of Syphilis,* July, 1926) emphasize the following points:

1. Neurosyphilis in severe form occurs very early in the course of syphilis, sometimes almost at the very start. These cases usually are of the mesodermic neurosyphilitic type, that is, the meninges are involved by a gummatous type of infiltration. These cases yield fairly readily to treatment, and potassium iodid is still of importance in their treatment.

2. The nervous system may be involved by the mesodermic changes later on in the course of syphilis, but in such cases there is usually parenchymatous involvement as well, and the prognosis is not very good.

3. It is to be emphasized that the Wassermann in the blood has, practically speaking, no relationship to neurosyphilis, and that where neurosyphilis is suspected, spinal fluid findings are imperative.

4. Certain cases of anterior horn involvement in neurosyphilis may be coincidental rather than have any causative relationship to the syphilitic process.

5. The authors believe that hypertension and neurosyphilis are probably too frequently associated to be merely coincidence. Even in old people, hemiplegia or cerebroarterial disease brings up the question of neurosyphilis as an important factor, and the spinal puncture as a routine in all cases of hemiplegia is strongly urged.

PEDIATRICS

Health Diagnosis in Children.—William R. P. Emerson (*American Journal of the Medical Sciences,* May, 1926) says that present schemes of health "chores," "teaching health," and so forth, are ill adapted to real needs and misleading in the impressions they actually make upon children. Intellectual knowledge has little or no permanent effect on health habits. The work of the school physician usually amounts to a mere "screening" out of a certain number of "deviations from the normal" without getting at causes or removing them. "Blanket," "shot gun" and panacea methods lead to waste of time, energy and funds much needed for constructive health work which takes account of actual causes and individual needs.

The basis of a program which deals with the entire period of growth is found in the present expert system of care worked out for the first year of infancy. Adequate provision for proper growth and development requires constructive health diagnosis which utilizes training in pathology without being overshadowed by it. This calls for adequate physical growth and social examinations to determine the causes of any failure to realize proper physical development and health.

A study of the results of thousands of these examinations show that the most common causes of physical unfitness are: 1, physical defects, especially nasopharyngeal obstructions; 2, overfatigue; 3, inadequate home or self control; 4, faulty food and food habits; 5, faulty health habits.

A similar study of health habits indicate that good health is found in those persons who practice good health habits and bad health is the accompaniment of faulty health habits. It is also evident that health habits and the state of healh do not improve with advancement in school or college grades. For instance, seniors in the medical school do not show better conditions than appear among college freshmen.

A satisfactory program takes account of this state of affairs and brings into operation the forces of: 1, The interest of the individual; 2, the home; 3, the school or college; 4, medical care, in order to remove causes of physical unfitness, bring the individual to a point where he is free to gain and afford him adequate training in proper health habits.

Application of this program has practically eliminated underweight and malnutrition from fourteen orphan asylums. It has been put into successful operation in many communities from Labrador to the Hawaiian Islands including cities in which a thousand or more children have been under care at one time with immediate and permanent improvement in weight and physical fitness. In various colleges the program has served to remove a large part of the physical unfitness among freshmen and upper classmen alike, demonstrating its efficiency throughout the whole period of growth and development.

Accurate and scientific methods are as necessary in diagnosing health as in diagnosing disease and the application of this principle is essential if we are to obtain permanent and satisfactory results.

Anorectal Prolapse in Children.—C. L. Heald (*Surgery, Gynecology and Obstetrics,* 42:6) describes a simple, bloodless operation for dealing with this pathology in children, when operation becomes, perchance, necessary. The intestinal tract is evacuated with milk of magnesia the day before, and by enema two hours before the operation.

Under ether or ethylene anesthesia the child is placed in the dorsal position, its legs being supported by an assistant. After the prolapsed bowel is reduced, a small bivalve rectal speculum is introduced, the blades spread laterally and the lower rectal mucosa swabbed with one per cent. aqueous solution of mercurochrome. A small rectal retractor on the anterior rectal wall may be used instead of the bivalve speculum.

The index finger is inserted and the notch or angle at the junction of the coccyx and sacrum is located.

A three inch, with a three eighth circle curved needle on one end of a coarse silkworm gut is passed along the finger in the rectum, inserted through the posterior rectal wall, through the notch at the sacrococcygeal angle and out through the skin posteriorly. A needle on the other end of the suture is passed in the same manner at the same point on the opposite side of the coccyx. A second, similar suture is placed one half inch lower, emerging on each side of the coccyx.

The sutures are tied rather tight over a folded gauze compress. The gauze may be kept dry by covering with rubber dam sealed to the skin with narrow strips of adhesive which are protected from moisture by painting with rubber cement.

The child is kept in bed for three or four days during which time bowel movements are prevented by small doses of paregoric twice daily. When it is desired to move the bowels an enema of three or four ounces of warm olive oil is given at night, to be retained, and milk of magnesia is given the following morning. The sutures are removed at the end of two weeks.

The efficacy of this method lies in the well-known tendency of silkworm gut to cut its way through the tissues, when under tension. As the suture slowly cuts through the rectal wall and perirectal tissues, healing by granulation follows in its track with the formation of firm connective tissue adhesions.

Primary Pneumococcus Peritonitis in Children.—A. H. Montgomery (*Surgery, Gynecology and Obstetrics,* 41:6) presents a case which he treated by immediate operation, commenting as follows:

There is probably a rather general idea among surgeons that the encysted cases should be watched until they are well localized. They may then be drained with a fair degree of safety. In the diffuse form the problem is more difficult. It is true, no doubt, as Kahn has stated, that we cannot drain the peritoneal cavity by any operative precedure. There is, however, in these cases a certain amount of intraabdominal pressure that tends to increase the absorption of toxins by the peritoneum. This intraabdominal tension can be relieved by a simple opening of the abdomen and the insertion of drainage. The operation should be as brief and nontraumatic as possible. The patient should then be put to bed in the Fowler position and kept at rest with morphine. Plenty of water must be given by rectal drip or subcutaneously. Hot packs may be used on the abdomen if they do not disturb the patient. In the diffuse form of primary pneumococcus peritonitis this combination of immediate simple operation, absolute rest, and strong supportive treatment has given us more favorable results than the supportive treatment alone. Under the latter only too many paients die unfortunately before any localization can take place. The operative treatment would seem to give them a somewhat better fighting chance.

Appendicitis in Infancy and Childhood.—S. J. Seeger (*Surgery, Gynecology and Obstetrics,* 42:4) finds that appendicitis is rare in the first two years of life. When occurring in children there is a tendency to early perforation, so that, with few exceptions, it should be treated surgically at whatever stage the patient is seen. The McBurney incision is the incision of choice because it gives rapid and bloodless access to the appendix and as a rule very little intraabdominal manipulation is required when this incision is used. Dehydration is an important factor and should always be considered in the preoperative and postoperative management of these children. It is best combated by the subcutaneous administration of fluids.

Etiology and Healing Process of Duodenal Ulcer in Melena Neonatorum.—Careful search in the literature reveals peptic ulcer in a larger number of cases of melena neonatorum, according to Roger L. J. Kennedy (*American Journal of Diseases of Children,* May, 1926), who has a case to contribute. It is believed by the author of the article that streptococci or diplococci must be the chief etiologic agents. Healing of duodenal ulcers begins very early and proceeds rapidly, so that under proper conditions the injury may be entirely repaired in a few days, an additional reason why they are so difficult to find. The rapidity of the healing of duodenal ulcer probably accounts for many of the recoveries from melena neonatorum.

The Prevention of Rickets.—May G. Wilson (*American Journal of Diseases of Children,* May, 1926) presents an interesting set of conclusions from an investigation of the therapeutic value of cod liver oil in rickets with infants in an outpatient clinic. Some of these conclusions are given below.

An intensive study of forty-seven infants, aged from two weeks, born in the winter of 1925, receiving daily doses of one, two, and three teaspoonfuls of biologically tested cod liver oil, showed the development of clinical rickets in sixty-

eight per cent. of the cases, as compared with seventy-six per cent. of the control series of thirty cases.

Ninety-seven per cent. of infants born in the summer, and ninety-one per cent. of infants born in the winter who received cod liver oil showed röntgenographic evidence of rickets.

The early age incidence of the development of rickets observed, indicates the necessity for measures of prevention or control to be instituted in the first month, particularly for babies born in the winter.

There did not seem to be any relation between the degree of rickets observed and the amount of cod liver oil received.

The concentration of calcium and inorganic phosphorus in the serum of infants under five months of age, with early clinical and röntgenographic evidence of rickets was found to be within the normal range.

A comparison of the degree and incidence of rickets observed in infants receiving and not receiving cod liver oil did not reveal any striking difference.

Infants receiving cod liver oil showed rickets that healed earlier than that of the control series.

The nature of the relation of cod liver oil therapy to the development of rickets, as observed in the studies, would seem to be one of control rather than of prevention.

Fetal Hydrops with Erythroblastosis.—Feeling the obligation of reporting an uncommon occurrence, Edward A. Bullard and Alfred Plaut (*Archives of Pediatrics,* May, 1926) relate a case of fetal hydrops with erythroblastosis. Seven years before this pregnancy the mother had given birth to a normal male child; the labor, though dry, was of only four hours' duration and ended in a spontaneous easy delivery. A second male child born five years later died on the third day apparently from hemolytic jaundice and pneumonia. A third child, a girl, died on the fourth day of life from cause unknown. An autopsy was refused. The mother who seemed a robust, vigorous normal woman was referred to Dr. Bullard during the last pregnancy.

Between the third month and delivery she had three attacks diagnosed as "Menière's disease, classical and unmistakable." The medical attendant advised no special treatment for this during pregnancy. Early in the seventh month the mother was delivered of a male child apparently dead several days. The weight was eight pounds. An extended autopsy led to the diagnosis given above.

Properties of Some Fabrics Used for Infants' Underwear.—Contrary to popular belief, knit cotton appears to be definitely warmer than wool, weight for weight, says Dr. Harold K. Faber in a communication on properties of some fabrics used for infants' underwear (*Archives of Pediatrics,* May, 1926). Silk is slightly less warm than wool.

Silk, cotton, wool, linen, birdseye cotton, and canton flannel are also compared, first as to ability to absorb body moisture in reasonable amounts depending on wetting properties and capacity for holding water; second, porosity, to permit passage of air to and from the skin; third, ability to withstand efficient cleansing, and preferably boiling, without rapid deterioration; and fourth smoothness of texture and surface, to prevent irritation of the skin.

Of the diaper material, birdseye cotton seems to be the best, although it has not as great a total capacity for water as canton flannel.

Appendicitis in Children under Five Years of Age.—Following an interesting and descriptive article Frederick Christopher (*American Journal of Diseases of Children,* April, 1926) concludes briefly as follows:

1. The most important factors in making the diagnosis of acute appendicitis in children under five years of age are elicitation of tenderness in the right lower quadrant, leucocytosis, rigidity in the right lower quadrant, and abdominal pain, named in order of their value.
2. The diagnosis may be extremely difficult.
3. Acute appendicitis occurring in patients under five years of age is characterized by rapid progress to perforation and gangrene, and has a high mortality.

Paratyphoid Fever in an Infant.—A case of paratyphoid fever in an infant, aged eighteen months, is presented by David Gingold and Harry Wexler (*American Journal of Diseases of Children,* April, 1926). The salient clinical features were persistent abdominal pain of three months' duration, marked secondary anemia, a relatively brief febrile period, and isolation from the blood of Bacillus paratyphosus B. It has been indicated by Stolkind and Lorey that paratyphoid fever in children is not so rare as the current literature and textbooks would suggest.

Uric Acid and Creatinin in the Urine of Infants.—S. Rougichitch (*American Journal of Diseases of Children,* April, 1926.) The uric acid excretion per twenty-four hours was measured in a series of twenty-two male infants. The diet of the infants being purin free, the amounts of uric acid found are regarded as of endogenous origin. A closely constant daily excretion was found for the individual. Measurements of urine creatinin in the same group of infants supported the conception of a close constancy of creatinin excretion in terms of the protoplasmic mass of the body. No relationship of creatinin excretion to differences in sleeping time or of muscular tonus was discernible.

Disseminated Tuberculosis in a Girl of Seven Years.—Jacob Sobel and J. Geiger (*Archives of Pediatrics,* April, 1926) describe a case of disseminated tuberculosis in a girl of seven where erosion of lymph gland into the right internal iliac artery resulted in a fatal hemorrhage. The child had been referred as an emergency case of appendicitis, and operation had been performed in spite of an atypical blood count. It was not until after the child had recovered from the operation that a complete examination suggested miliary tuberculosis.

The questions then arising are: 1, Can ileocecal tuberculosis be differentiated with positiveness in the pre-operative stage? 2. In the light of the history that this child had not been seriously ill prior to the acute onset which brought her to the hospital, is it probable that the intraabdominal tuberculosis was primary? 3. If this child had not been subjected to operation, would the course of the disease have been less rapid and less diffuse?

Death Following the Inhalation of Zinc Stearate.—Karl Shlaepfer (*American Journal of Diseases of Children,* April, 1926) reported as another fatality after the inhalation of zinc stearate in a child, aged seven and one-half months old. Death followed in thirty-four hours. Cyanosis and dyspnea characterized the clinical course of the illness, and a state of socalled acidosis was noted after the patient was admitted to the hospital, twelve hours before death. At necropsy the lungs were voluminous. Extensive areas of emphysema were separated from each other by small, scattered, atelectatic zones. The bronchioles contained plugs of zinc stearate and mucus which appeared as wormlike masses. Edema involved the alveoli, and the subpleural and interlobular connective tissue septums. The lymphatics throughout the lung were conspicuously dilated.

In spite of oxygen inhalation, persistence of the dyspnea may have been due to acidosis brought about by incomplete obstruction to the bronchioles with zinc stearate.

Ekiri: an Epidemic Infantile Diarrhea.—Japanese ekiri is thought by Keiji Kawata (*Archives of Pediatrics,* April, 1926) to be the same as cholera infantum and American summer diarrhea. It has exacted a high toll from children between two and six years of age but never affects nursing infants. Customary treatments of large and repeated doses of castor oil, with rectal infusion of lukewarm water, ice bag on the head, keeping the legs warm by hot water bottles, subcutaneous injection of saline fluid or Ringer's solution, and sometimes antidysenteric serum did not diminish the mortality.

The author studied the character of cramp and sudden weakening of the heart in the sickness. Remlinger and Dumas, of France, attested the presence of inflammatory swellings of the suprarenal glands in dysenteric corpses. Yasuda also detected the same change in ekiri. The disorder of the heart in diphtheria and other infectious diseases is traceable to the functional insufficiencies of the suprarenal glands.

In 1908 Pospischill, of Vienna, relieved heart weakness in diphtheria by using adrenalin. Taking these facts into consideration, as he says, the author began the application of adrenalin, together with rest and plenty of water and out of a total of eighty-one cases in the last seven years receiving the above treatment the mortality has been reduced to 7.4 per cent. During a four year period in the Fukuoka prefecture the mortality had been 59.7 per cent. while during a six-year period in the Gifu prefecture the mortality had been 82.4 per cent.

Syphilitic Endarteritis in Children.—From two cases of syphilitic endarteritis with gangrene, Harry M. Gilkey and C. C. Dennie (*American Journal of Diseases of Children,* April, 1926) conclude that syphilitic endarteritis involving the skin of extremities of children is more amenable to treatment than the ordinary type.

Hexylresorcinol in the Treatment of Pyelitis of Infancy and of Childhood.— A grateful substitute for renal pelvic lavage in young children is supported by William J. Scott and Veader Leonard (*American Journal of Diseases of Children,* February, 1926) who report favorable results in twelve cases with hexylresorcinol. The properties in its favor are several. It is a stable chemical compound, nontoxic in therapeutic doses, nonirritating to the urinary tract, bactericidal in high dilution in urine of any reaction, and is eliminated by the kidney after administration by mouth, unchanged, in sufficient concentration to impart active bactericidal properties to the urine. To obtain the best results, the authors recommend that the treatment should be persistent, the fluid intake should not be increased, and soda should be avoided during administration of the drug.

Splenic Diseases with Special Reference to Splenectomy in Children.—I. Russel Kuhn (*Archives of Pediatrics,* June, 1926) remarks that the spleen, even though its function may not even at the present time be fully understood, may best be considered as a filter placed in the blood stream under normal conditions to filter the red blood cells which disintegrate daily. It is the graveyard of the red blood corpuscles. Under pathological conditions, cells foreign to the circulation, as nucleated red blood cells, myelocytes, bacteria and other toxic agents, are also filtered out, the retention of which adds greatly to the increase of the size of the organ.

Splenectomy, generally speaking, is contraindicated in the leucemias and pernicious anemia. In Gaucher's disease and von Jacksch's anemia removal of the spleen should be undertaken only after the greatest deliberation. In many cases of Banti's disease, congenital family hemolytic jaundice and purpura hemorrhagica, splenectomy is definitely indicated. It is firmly established that the spleen is not necessary to life and the improvement in surgical technic has transferred the treatment of many of its diseases from the internist to the hands of the surgeon.

The Serum Prophylaxis of Measles by Means of Blister Fluid.—P. Modinos (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris,* March 18, 1926) notes that the great practical value of the serum prophylaxis of measles has hitherto been reduced by the difficulty of obtaining the serum. In a recent epidemic the expedient of using serum obtained, not by vein puncture, but by the application of a vesicant was adopted with complete success. Such serum, injected in three to five mil amounts, produced immunity in other children living in the same house with the patient and who had been in contact with him from the onset of the disease. It is much easier to obtain ten to fifteen or twenty mils of serum by blistering a child of six to ten years than to collect the same amount by vein puncture, which is difficult to carry out in small children. Each individual blistered will yield enough serum to immunize three or four persons. Another advantage of the procedure relates to the transmission of other diseases. Transmission of malaria is precluded by the author's earlier observation that the plasmodium never occurs in blister fluid, even during severe malarial paroxysms. As for tuberculosis and syphilis, not only are they more common in persons over twenty years of age than in children, but when they do occur in children their manifestations are so distinct as to be recognized at the first glance.

Double Inguinal Hernia in Infancy.—John T. Morrison (*Lancet,* March 27, 1926) maintains that by means of a one and a half inch incision along the line of the crest of the pubis efficient access may be obtained to either external abdominal ring. The incision is deepened till the surface of the aponeurosis is reached. A small double hook retractor is placed in the angle of the wound, and with quite moderate traction the region of the abdominal ring is exposed. An oblique incision through soft parts parallel to Poupart's ligament discloses the cord and its coverings. The operation can then be completed in the ordinary way.

After dealing with one side the operator exposes and treats the other exactly in the same way. By this maneuvre the time of the operation can be very materially reduced. In cases where it is desired merely to explore the opposite side this incision is particularly useful, and if no hernia be found the additional time taken is never more than a minute or two. Such a necessity may easily arise in infants in whom the presence of a hernia on the opposite side is easily overlooked. In conclusion, another advantage is the fact that the transverse suprapubic incision does not, as a rule, involve the use of any artery forceps, as neither superficial epigastric, nor superficial external pubic arteries need be divided. By this means further time saving is effected.

Diphtheria Following Tonsillectomy.—In connection with a case cited, Dr. Abraham Zingher (*American Journal of Diseases of Children,* January, 1926) says that diphtheria is likely to develop in a patient who has just been operated on for tonsillectomy and adenoidectomy, if the person is susceptible, as can be shown by a Schick test, and if he is a carrier of virulent diphtheria bacilli. While these three factors—absence of general immunity to diphtheria, presence of virulent diphtheria bacilli in the nose or throat and an operation, such as tonsillectomy—may not come together frequently, yet when they are present in the same person, diphtheria is quite certain to follow and the disease is likely to prove very dangerous, possibly fatal. The serious nature of the superimposed diphtheria arises from the danger of an early and rapid absorption of a fatal dose of toxin from the extensive raw surface, and the difficulty of recognizing the disease in the sloughing postoperative membrane until much valuable time has been lost and the opportunity for effective administration of antitoxin has slipped by.

Diphtheria may also readily develop as a result of a superimposed infection with diphtheria bacilli occurring in a susceptible person from one to two weeks after an operation on the tonsils and adenoids. At this time the wound has not completely healed, and the resistance of the mucous membrane to infection is still below normal.

CARDIOVASCULAR DISORDERS

The Cardiovascular Patient.—F. H. Laney and B. E. Hamilton (*Surgery, Gynecology and Obstetrics,* 42:2) direct attention to the method with which they have succeeded in rehabilitating patients with cardiovascular disease by indirect surgical measures. This consists in the removal of surgical burdens. The order of the greatest degree of accomplishment is removal of the toxic goitre, removal of large pelvic tumors, and removal of troublesome gall bladders.

In view of our low mortality with this type of cases, we urge that patients in this group who have coincident and burdensome surgical lesions, after proper consideration and preparation by rest, and partial or complete restoration of compensation, be operated upon and relieved of such lesions. It has been our experience that if there is cooperation between cardiologist, anesthetist, and surgeon, not only will the mortality in this seemingly hopeless group be surprisingly low, but the degree of restored ability in many cardiovascular cases will be strikingly high.

Cancer of the Heart.—R. Kapsinow (*Annals of Surgery,* Vol. 83:2) describes an unusual case of cancer of the heart, secondary to that of the breast. The distribution therein indicated that the growth was a retrograde invasion by direct continuity along the lymphatic channels of the anterior mediastinum to the base of the heart, and thence extending downwards through the hepatic channels involving the liver, gallbladder and pancreas. Judging from the size alone, the invasion of the heart preceded the abdominal growths by several months.

The Etiology of Heart Disease.—J. Edwin Wood, T. Duckett Jones, and Ray D. Kimbrough (*American Journal of the Medical Sciences,* August, 1926) have studied 623 cases of heart disease and made the following observations concerning race and climate. Organic heart disease is almost twice as common in the negro as in the white. Hypertension and syphilis are the chief etiological factors producing heart disease in the negro. Angina pectoris is less common in the negro than in the white, despite the fact that syphilis and arteriosclerosis are such important factors. Rheumatic heart disease is almost twice as common in Massachusetts as in Virginia, and this is the largest etiologic group in the former locality. Hypertension as an etiological factor in heart disease is somewhat more prevalent in Virginia than in Massachusetts, but comprises a large group in each instance.

Thyroid Operations and Goitre Heart.—J. S. Goodall (*International Journal of Medicine and Surgery*, 39:1) calls attention to the fact that in goitrous conditions the heart may be affected either mechanically, its action being embarrassed by the pressure of the enlarged thyroid on the great vessels and other structures at the root of the neck, or chemically by exposure to the influence of the toxic products of thyroidism. Both of these factors may, of course, operate together.

In many goitre cases one of the indications for operation is the protection of the myocardium, but in all the condition of the myocardium is the indication of the nature and extent of any operation.

Etiological Factors in Angina Pectoris.—Morris H. Kahn (*American Journal of the Medical Sciences*, August, 1926) discusses the etiological factors found in eighty-two cases. Almost twenty-five per cent. of the cases had their first typical attack before the age of forty years. The sex proportion was 65 males, 17 females. Tobacco and alcohol could not be excluded as contributory factors. Sudden excessive strain is the most important immediate factor preceding the attack, and its effect is more likely to be injurious in individuals engaged in moderate or sedentary occupations in whom the heart and aorta have not been trained to accept sudden strain adaptably. Acute infectious causes such as rheumatism and infected tonsils appear to be important in initiating vascular changes in the aorta and coronary artery area. In only three cases was syphilis a factor. Diabetes was present in ten cases of angina pectoris. There was no direct etiological relation between arterial pressure and the attacks. Gallbladder disease coexisted in three cases.

Treatment of Substernal and Precordial Pain.—Thomas F. Cotton (*Lancet*, April 17, 1926) states that the treatment of primary angina is that of heart failure. The patient must live within the limits of his exercise tolerance. Those activities, physical or mental, likely to provoke pain must be avoided. The daily life should be supervised and the patient should be allowed a sufficient amount of exercise and no more—all that he can do comfortably without pain. His occupation should be one that does not exhause or unduly tire the damaged myocardium. The diet should be an easily digested one, erring on the side of low caloric values; small meals slowly eaten, and well masticated, and taken with a minimum of fluid. It is important to rest after meals, for pain is easily provoked at this time. The general laws of hygiene should be rigidly obeyed. All foci of sepsis should be removed. Cold winds or exposure to dampness should be avoided. Sleep should be aided by suitable sedatives (bromides and chloral) if there is a tendency to insomnia.

When the anginal attack is severe and persists with the patient at rest amyl nitrite may relieve the pain. Morphine is well tolerated and can be given in large and repeated doses. Chloroform inhalations alone relieve some patients, especially when the anginal attack is caused by thrombosis or embolus in coronary vessels. Sodium nitrite, one grain, slowly dissolved in the mouth a quarter of an hour before beginning such exercise as walking, may prevent the onset of expected pain. Diuretin given in doses of ten grains over a prolonged period is useful. In a nervous patient it is helpful to add potassium bromide, ten or fifteen grains to the diuretin, and give it in a mixture. Potassium bromide may also be given with potassium iodide, ten grains, especially in hypertension cases. With a history or signs of syphilis, the usual mercurial treatment with potassium iodide over a prolonged period is indicated. Each year a course of arsphenamine treatment should be given. Diathermy, three treatments a week over a period of a month, is helpful in some cases.

There is no sound reasoning to support the surgical treatment of angina, but there is some evidence that benefit in primary angina has followed the Jonnesco operation of cervical sympathectomy. The results from other operations should await confirmation before being tried.

In secondary angina we must rely on removing the primary cause of the disease. The body should be explored for structural disease, sepsis, or some functional derangement; treatment should depend upon the result of such an examination. The same line of treatment as for primary angina is also indicated. It is important, for its psychological effect on the patient, to emphasize the secondary nature of the heart affection.

In neurasthenic cases it is important to stress the symptoms which can be explained on other grounds than those of cardiac disease, and to avoid emphasizing such symptoms as are cardiac in origin. If the symptoms can be attributed to the stomach the treatment then becomes one of diet, carminative mixtures, and a judicious use of sedatives. Many of the drugs recommended for the treatment of primary angina can be usefully given in cases of angina of this type.

Potency of Tinctures of Digitalis and Strophanthus Purchased at Various Points on the Canadian Market.—F. W. Ward (*Canadian Medical Association Journal*, April, 1926) says that the variation in potency of tinctures of digitalis and of strophanthus run parallel. Some samples are eighty per cent. below standard and others four hundred and thirty per cent. above standard. The variation between manufacturers' preparations is very marked, and the variation between samples of the same manufacturer is also marked. Before using, it is necessary to observe whether the tincture is marked as concentrated or not. From these results it must be concluded that tinctures of digitalis and strophanthus marked "B. P." as at present met with in Canada are very variable in their potency. The designation B. P. has no other significance than that the tinctures have been prepared in a certain way and is no criterion as to their potency. The designation U. S. P. may be some guide as to the potency, but this will depend on the reputation of the manufacturers and how honestly they have lived up to the U. S. P. standard. It is to be regretted that in no case is the standardization of these preparations as yet subject to governmental control in this or any other country.

Continued Adrenalin Treatment in Asthmatics with High Blood Pressure.—G. Etienne, G. Richard and F. Claude (*Bulletins et mémoires de la Société médicale des hôpitaux de Paris*, March 18, 1926) discuss the case of an asthmatic with hypertension who used intramuscular injections of adrenalin to a total of 800 milligrams in the course of the year 1924. At the end of this time the blood-pressure had not only not increased but returned to normal. There was no evidence of atheroma on fluoroscopy of the aorta, and the patient's vegetative reactions continued to show a tendency toward vagotonic preponderance, in spite of the adrenalin. During 1925, adrenalin was further used to a total of 1,215 milligrams. Fluoroscopies showed no special opacity of the aorta. The blood-pressure remained fixed at the levels noted in the previous year, viz., 140 and 70 millimetres. Slight vagal preponderance continued. The patient was in excellent general health and had resumed an active life, which had not been possible previous to the use of adrenalin. This and other clinical observations made by the author as well as Ricaldoni, Maira and Münzer on asthmatics with hypertension treated by large, repeated doses of adrenalin show that there is no absolute contraindication to the use of this drug in high blood-pressure.

The Blood Cholesterin in High Blood Pressure.—G. Richard and J. Roesch (*Bulletin de l'Académie de médecine*, March 30, 1926) report a study of the relationship of the blood cholesterin to hypertension in eighty cases. In thirty patients with a systolic pressure between 150 and 200 millimetres of mercury, the average blood cholesterin was 2.06 grams. In twenty-four patients with a systolic pressure of 200 to 250 millimetres, the average was 2.12 grams. In twenty-six patients with a pressure of 250 or over, the average was 2.17 grams. Thus, there is a rise of cholesterin in hypertension, but it is too slight to warrant the view of a proportional relationship between the two. Similar considerations apply to the diastolic pressure. In thirty-four patients with the blood cholesterin normal or below two grams, the average blood urea was 0.41 gram. In forty patients with cholesterin between two and three grams the blood urea averaged 0.44. In six patients with cholesterin exceeding three grams, the blood urea averaged 0.38 gram. Thus, while hypercholesterinemia is very often associated with Bright's disease, the blood urea does not seem to govern the blood cholesterin; indeed, as Chauffard, Laroche and Grigaut have maintained, the cases with the most pronounced nitrogen retention are those which show the least increase in blood cholesterin. A noteworthy feature was that all the patients who suffered from pronounced chronic headache showed a high blood cholesterin with relatively low blood urea and blood pressure.

Medicolegal Notes.

EMPLOYEE HAS BURDEN OF PROOF OF FAILURE OF HOSPITAL TO GIVE PROPER TREATMENT UNDER CONTRACT WITH EMPLOYER

A hospital contracted with a coal mining corporation to furnish the company's employees with necessary hospital treatment for injuries received in the course of their employment, for a consideration paid by each of the employees. An injured employee was immediately taken to the hospital, after his hips and pelvis were crushed when he was caught between the bumpers of two coal cars. He was treated and operated on, some of the broken bones were removed, and his wounds dressed. After about 30 hours treatment, he was removed by his father and friends to another hospital, where he was treated until he recovered and was discharged. He sued the first hospital to recover the amounts he paid the second, under West Virginia Code, section 2, c. 71, on the ground of breach of his contract with the defendant. The West Virginia Supreme Court of Appeals held, Meadows v. McCullough, 132 S. E. 194, that the burden was on the plaintiff to prove that the defendant hospital did not furnish to him such necessary professional treatment in the said hospital as was contemplated by the contract, and such as is ordinarily furnished at hospitals of like kind and character in the same community, acting under like circumstances, and, further, that such failure was not the result of the plaintiff's act. It was held that a verdict should have been directed for the defendant, there being no evidence to show failure to give the plaintiff proper treatment under the contract.

LIABILITY FOR MEDICAL SERVICES TO PRISONER IN CUSTODY OF SHERIFF

In an action by a physician and surgeon owning and operating a hospital, for professional services rendered and hospital expenses incurred for a prisoner at the request of the sheriff, against the sheriff and the board of county commissioners, the North Carolina Supreme Court held, Spicer v. Williamson, 132 S. E. 291, that, under the general rule that a mere request by a person to a physician to render services to another to whom the person making the request is under no obligation to furnish medical care raises no implication of a promise to pay for the services, a sheriff or other officer is not under a legal obligation to provide medical attention for a prisoner in his custody for payment of which he is personally liable. Whether the sheriff expressly agreed to pay plaintiff for his services to the prisoner was a question for the jury. The burden of proving such an express agreement was on the plaintiff.

It is held to be the duty of the board of commissioners of a county in North Carolina, under Comp. St. §§ 1317, 1346, 1347, to provide for necessary medical attention to a prisoner confined in the county jail, whether the prisoner has been committed to jail as a result of a preliminary trial or upon a final judgment on his conviction of a violation of law. This duty is owing to a person, lawfully in the sheriff's custody, awaiting a preliminary trial and confined in jail because of his inability to give bond for his appearance at the trial, and the duty is extended to a person in the lawful custody of the sheriff, who is unable because of the condition of the prisoner, to take him at once to jail. The fact that the board had not authorized the sheriff to request the plaintiff to render professional services to the prisoner did not, under the facts of the case, relieve the board of liability for the reasonable value of the services. Ordinarily, the sheriff should report the condition of the prisoner to the board before calling in a physician. In an emergency, however, such as existed in this case, a shot wound received while resisting arrest, the sheriff may, it was held, without previous authority from the board, procure necessary attention for the prisoner, and the board will be liable for the reasonable charge for such services as may be rendered to the prisoner at the sheriff's request. Whether or not the services rendered and hospital expenses incurred were reasonably necessary in view of the prisoner's condition while in the sheriff's custody was a question for the jury.

COUNSEL CANNOT TESTIFY AS TO CORRECTNESS OF X RAYS

The Texas Court of Civil Appeals holds, Lumbermen's Reciprocal Assn. v. Wells, 283 S. W. 208, that counsel for plaintiff in a personal injury case was incompetent to testify that x ray pictures of plaintiff's injured leg and ankle, offered in evidence and exhibited to the jury, were correct and that the doctor taking them "was a competent man to use the scientific method of taking this character of pictures, and to know that he was properly equipped for such business," there being nothing in the record to indicate how counsel could know these facts.

UNAUTHORIZED RAILROAD CLAIM AGENT CANNOT BIND COMPANY FOR MEDICAL SERVICES TO EMPLOYEE

In an action against a railroad company for professional services rendered and medicines furnished to an employee of the company, the theory of the plaintiff's case was that the company was obligated to pay the doctor's bill by the words and conduct of its claim agent. The Georgia Court of Appeals held, Copeland v. Southern Ry. Co., 133 S. E. 271, that, since neither the evidence for the plaintiff, nor that for the defendant, nor both together, showed that the claim agent had authority to bind the company to pay the bill in question, the plaintiff could not recover.

PHYSICIAN'S TESTIMONY AS TO PLAINTIFF'S CONDITION BEFORE AND AFTER INJURY ADMISSIBLE

The Kentucky Court of Appeals holds, in an action for personal injuries, Chesapeake & O. Ry. Co. v. Hanson, 283 S. W. 86, that the testimony of plaintiff's family physician that he had not treated her prior to the accident, but that since then he had treated her for painful menstruation, although he was unable to say whether or not this was the result of the accident, was admissible, although there was nothing to show that this ailment was the result of the injury, in view of the fact that it was not made the basis of a recovery for permanent injuries, but was a statement of a physical fact regarding plaintiff's condition before and after the injury and part of the history of the case.

IMMUNITY OF MUNICIPAL HOSPITALS FOR LIABILITY TO INJURED EMPLOYEES

The Kentucky Court of Appeals holds, Zachert v. City of Louisville, 282 S. W. 1071, that the city of Louisville, being clothed, by authority of the state Constitution and the provisions of its charter, with the power to erect, establish, and maintain hospitals, almshouses and other buildings for the preservation of the public health, is not responsible to persons injured because of the misconduct or negligence of its agents and employees in a hospital which it has established for charitable purposes, whether the person injured be a patient of the hospital or an employee therein. The action was by a servant of the hospital for injuries to her face, head and other parts of her body caused by the explosion of the boiler or drum of a steam sterilizer which she claimed resulted from the opening by her of the boiler door by order of a nurse whom she was attending as helper. The negligence claimed was in permitting the boiler to become overcharged and failing to shut off the steam.

After Depressing or Exhausting Ills

such as tonsillitis, La Grippe, influenza, pneumonia, the eruptive fevers, diphtheria, and the severe colds with their all too often complications and sequelae, effective restorative treatment is invariably needed. The recuperative powers of the body need to be aided and supplemented, and no remedy will be found more serviceable and effective at this time than

Gray's Glycerine Tonic Comp.

(*Formula Dr. John P. Gray*)

Given in dosage appropriate to each individual, there follow an immediate improvement in the circulation, a gratifying increase in the activity of all vital functions, and a noteworthy gain in the bodily nutrition that are promptly reflected in the patient's weight, appearance and feeling of well being.

In brief, the systematic use of "Gray's Tonic" means a rapid convalescence and an early and satisfactory return to health.

Valentine's Meat-Juice

For **Quieting** the **Irritable Stomach, Aiding Digestion** and **Sustaining** and **Strengthening, Valentine's Meat-Juice** is employed in Hospital and Private Practice in the treatment of

Diseases of Children.

W. B. Scranton, M. D., *Medical Superintendent, Korean Mission Methodist Episcopal Church, Seoul, Korea:* "A most excellent use I frequently put VALENTINE'S MEAT-JUICE to is tiding Babies through Cholera Morbus and the Wasting Diseases incident to Summer and Inanition. It acts at once, and many a crisis has been passed safely by my patients, through the agency of VALENTINE'S MEAT-JUICE. It has also been of great value in my practice in the Far East in the treatment of that form of Summer Diarrhoea known as Sprue, where it tides the patients over until they can get to a better climate, and the change of climate rectifies the rest."

VALENTINE'S PREPARATION
NUTRIO PER ME
VOLUME 1 4/5 OZ.
MEAT JUICE.
The result of an Original Process of preparing Meat and extracting its Juice by which the elements of nutrition are obtained in a State ready for immediate absorption.
DIRECTIONS. Dissolve one teaspoonful of the Preparation in three tablespoonfuls of cold or warm water; boiling water changes the character of the preparation.

For Sale by American and European Chemists and Druggists.

Miscellany.

Longevity of College Athletes.—In cooperation with the Presidents' Committee of Fifty on College Hygiene, the Metropolitan Life Insurance Company has begun an investigation into the effect of college athletics upon the life expectation of students who engage in them. Other organizations which are participating are the American Students' Health Association, the National Collegiate Athletic Association, and the Society of Directors of Physical Education in Colleges. The subsequent life histories of from eight to ten thousand college athletes, more particularly "letter men," who were members of the class of 1905 and prior years will be studied. The sports to be covered are football, rowing, track, baseball, lacrosse, cross country, and hockey. Thus far, the following universities and colleges are participating in the inquiry: Yale, Princeton, Cornell, University of California, University of Michigan, University of Chicago, University of Pennsylvania, and Amherst. Other institutions are expected to participate, but the inquiry will necessarily be restricted, as the majority of colleges and universities did not have, as early as 1905, well organized athletic departments.

There has been considerable discussion, both within and without university circles, on the effect of college athletics upon life expectancy. Opinion differs widely, and it is indeed fortunate that the subject is now to be studied intensively and scientifically.

Dr. Thomas A. Storey, director, department of hygiene, College of the City of New York, is executive secretary of the Presidents' Committee of Fifty, and is sharing with Dr. L. I. Dublin, statistician of the Metropolitan Life Insurance Company, in the direction of this investigation. Inquiries regarding this study and offers of cooperation from other university departments having records of their athletes available for study will be gladly received by either of the directors.

The Carnegie Foundation for the Advancement of Teaching is also interested in this project as a part of the Foundation's study of school, college and university athletics, in the United States.—*Statistical Bulletin.*

The Osaka (Japan) Sanitation Exhibition.—With a view to increasing the hygienic knowledge of the people and improving medical and sanitary supplies, a sanitation exhibition will be held in Osaka, Japan, from July 15 to August 30, 1926. The exhibition will be held under the auspices of the Federation of Sanitary Associations of Osaka, and with the support of the home office, the Osaka prefecture, and the Osaka municipality.

The exhibits will include all kinds of articles pertaining to sanitation and are divided into two classes or departments: Department A will consist of exhibits sent from Government and public institutions, and department B will include medical and sanitary supplies in general.

Official organizations, public institutions, and manufacturers who desire to display articles at this exhibition should send in their application at once, together with a list of exhibits, stating the number, size, value, and weight, in order that suitable space may be reserved.—*Public Health Reports,*

INTERESTING INVESTIGATIONS MADE AT THE HORACE GREELEY LABORATORY

April and May 1926, and by Dr. L. H. Cornwall, Bacteriologist New York City

36 new toothbrushes were purchased, placed in separate test tubes and sterilized.
Brushes were given to as many people. After cleaning the teeth each brush was rinsed in water and returned to its container.
Into each container was poured 10 cc of sterile 0.9 per cent saline (covering bristle end of brushes) and the containers returned to the ice-box for 24 hrs.
Brushes were then shaken out in the saline and removed from the tubes. Tubes were then well shaken and .01 of a cc of the contents of each was planted on a tube of Loeffler's blood serum and the latter incubated for 24 hours.
The saline remaining in the 36 tubes was then transferred to as many centrifuge tubes and centrifuged for five minutes at 2200 revolutions. Smears were made of the sediment and stained with methylene blue. Identification of organisms was made from their morphology in the above mentioned smears and in smears from cultures and replants, and peculiarities of growth in replants upon various media. Altogether some 500 cultures and 600 smears were made and examined.

FINDINGS IN CONDENSED FORM

36 (all) of the brushes showed Staphylococci, aureus or albus or both,
31 of the same brushes showed Pneumococci,
19 showed streptococci, non-hemolytic.
1 showed streptococci hemolytic.
11 showed Vincents angina.

10 brushes used only five days were examined by Dr. Cornwall for organic matter. It was demonstrated in every case.
12 brushes of diphtheria cases were examined. 9 showed diphtheria bacilli. One week later 8 of the brushes still showed diphtheria bacilli.

As a result of these findings how can we reconcile ourselves to the use of the toothbrush for practicing MOUTH HYGIENE.

RE VIRA

Provides a clean pad each time the teeth are cleaned and the gums massaged. Outfits, Adult's $1. Child's $0.75. Special price to Physicians and Dentists.

Activities of the Rockefeller Foundation.—A review of the activities of the Rockefeller Foundation in 1925.

During 1925 the Foundation in spending $9,113,730 through its departmental agencies, the International Health Board, the China Medical Board, the Division of Medical Education, and the Division of Studies, engaged in the following activities:

1. Aided the governments of eighteen countries to combat hookwork disease; 2, gave funds to the budgets of organized rural health services in 220 counties in twenty-six American states and in eighteen districts in Brazil, Poland, Czechoslovakia, Austria, and France; 3, took precautionary measures against yellow fever in Salvador, Guatemala, Nicaragua, and Honduras; 4, continued to work with Brazil in freeing its northern coast from this disease; 5, sent a yellow fever commission to the West Coast of Africa; 6, helped to show the possibilities of malaria control in twelve American states, and in Brazil, Argentina, and Italy; 7, shared in the development of professional training of public health officers at Harvard University and the University of Toronto and in schools and institutes in London, Copenhagen, Prague, Warsaw, Belgrade, Zagreb, Budapest, Trinidad, and Sao Paulo; 8, contributed to the progress of medical education at Cambridge, Edinburgh, Copenhagen, Brussels, Utrecht, Strasbourg, Beirut, Singapore, Bangkok, Sao Paulo, and Montreal; 9, provided emergency aid in the form of literature and laboratory supplies for 112 medical centres in Europe; 10, maintained a modern medical school and teaching hospital in Peking with 164 students and fifty-five teachers; 11, aided two other medical schools and nineteen hospitals in China; 12, helped to improve the teaching of physics, chemistry, and biology in three Chinese and seven foreign institutions in China and in the government university of Siam; 13, supported nurse training courses in Peking Union Medical College, Yale University, Vanderbilt University, and the George Peabody College for Teachers, and contributed to nursing education and service in Brazil, France, Yugoslavia and Poland; 14, provided current funds for an institute of biological research in the Johns Hopkins University; 15, assisted departments at Yale and Iowa State universities engaged in biological and mental research, and aided the Marine Biological Station at Pacific Grove, California; 16, provided, directly or indirectly, fellowships for 842 men and women from forty-four different countries, and financed the travel of fifty other persons either in commissions or as visiting officials and professors; 17, contributed to the League of Nations' international study tours or interchanges for 128 health officers from fifty-eight countries; 18, continued to aid the League's information service on communicable diseases; 19, made surveys of health conditions, medical education, nursing, biology, and anthropology in thirty-five countries; 20, lent staff members as advisers and made minor gifts to many governments and institutions; 21, assisted mental hygiene projects both in the United States and Canada, demonstrations in dispensary development in New York City, and other undertakings in public health, medical education, and allied fields.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

A Symposium on Cancer.—From September 20th to 24th the American Society for the Control of Cancer will hold a symposium on cancer at Lake Mohonk, Ulster County, New York. The meeting will be attended by about one hundred Europeans and Americans of foremost professional standing in relation to the cancer problem.

The names of the Europeans and the titles of the papers they will read are as follows:

ENGLAND

Sir John Bland-Sutton, president of the Royal College of Surgeons: The Value of Coordinated Effort Among Surgeons, Pathologists and Others in the Control of Cancer.

Dr. W. Sampson Handley, honorary surgeon, Middlesex Hospital: The Earliest Diagnostic Signs of Cancer Visible to the Patient, to the General Practitioner of Medicine, and Detectable by Investigation at Clinics and Hospitals.

Dr. Archibald Leitch, director of Research Institute, Cancer Hospital, London: Practical Value of Researches Into Contributory Causes of Cancer.

Dr. James A. Murray, director of the Imperial Cancer Research Fund: Some Notable Contributions to the Knowledge of Cancer.

FRANCE

Dr. Léon Bérard, professor of surgery, University of Lyons: The Organization and Practical Working of the Centres Against Cancer in France.

Dr. Henri Hartmann, professor of surgery at the University of Paris: The Objects and Methods of the Organized Movement Against Cancer in France.

Prof. T. Marie, director of the Anticancer Centre of Toulouse: The Need of Special Institutes for the Investigation and Treatment of Cancer, as Compared with Other Methods of Dealing with Cancer Patients.

Dr. Claude Regaud, director of the Pasteur Laboratory of the Radium Institute, Paris: The Value and Proper Equipment of Institutions for the Treatment of Cancer by Radium and X Rays.

Prof. Gustav Roussy, director of the Laboratory of Pathological Anatomy, University of Paris: Research in Relation to Prevention and Treatment.

GERMANY

Dr. R. Bierich, director of the Institute of Cancer Research in Hamburg: The Organized Movement for Cancer Control in Germany.

SWITZERLAND

Dr. Charles DuBois, president of the Swiss National League for the Control of Cancer: The Campaign Against Cancer in Switzerland.

DENMARK

Dr. Johannes Fibiger, director of the Pathological Anatomical Institute and Rector of the University of Copenhagen: Cancer Control in Scandinavia.

BELGIUM

Prof. J. Maisin, director of the Cancer Institute of the University of Louvain: The Organized Movement for the Control of Cancer in Belgium."

HOLLAND

Prof. H. T. Deelman, director of the Institute of Pathology of the University of Groningen: The Relative Mortality from Cancer Among Different Races.

Prof. William M. deVries, president of the Netherlands Cancer Institute: The Prevalence of Cancer as Revealed by Mortality Returns and at Autopsy.

Valentine's Meat-Juice

In **Typhoid Fever Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** of **Restoring** and **Strengthening.**

I. Burney Yeo, M. D., *Professor of Therapeutics, King's College, London, in the well known work, "Food in Health and Disease":* "In a very severe case of Typhoid, under our care in King's College Hospital, with most alarming and profuse hemorrhage, we carried out a rigorous method of feeding with remarkably satisfacory results. The clear indication was to keep the intestines absolutely at rest and to allow no debris of food to pass through to excite peristaltic action. It was necessary therefore to give food which, while adequate to sustain and strengthen the patient, should be wholly absorbed in the stomach and upper part of the small intestines. To give milk might be fatal. For our purpose we selected VALENTINE'S MEAT-JUICE, giving one teasponful in a wineglassful of cold water every three hours, with one teaspoonful of brandy. The patient's diet was absolutely limited to these quantities for seven days. The plan answered admirably and the patient made a perfect recovery and fairly rapid convalescence."

For Sale by American and European Chemists and Druggists.

Flying Doctors.—The distinguished specialist who flies once in a while to a rich, importunate, and distant patient is already familiar to most of us. Less is known of the systematic use of aeroplanes for the sick and injured, although the ambulance aeroplane has already done good service. It was first used by the French Army in Morocco under Marshal Lyautey. In May, 1921, twenty aeroplanes, each carrying two stretchers, were sent to Morocco, and proved so successful on evacuating the wounded that since then many more have been employed. The Swedish Red Cross has done pioneer work in using an ambulance aeroplane to transport the sick from its sparsely populated northern areas to the nearest hospital, often over one hundred miles distant. In 1923 it applied to the Government for a subsidy to purchase an aeroplane for this purpose, and the Government agreed to share the expense of purchase. The machine is piloted by military airmen, and the Red Cross defrays the running expenses. Many lives have been saved by this means. One patient, suffering from hemorrhage and living in a very isolated part, was transported in an hour and a half to the nearest hospital at Baden, whither the journey by sledge would have taken at least twenty hours. Once the idea had taken root its corollary became evident. If an aeroplane can take the patient to the doctor it can also take the doctor to the patient. This second lifesaving use for the aeroplane is particularly applicable to Australia, with its average population density of only 1.83 persons per square mile, and in the April number of *The World's Health* H. C. Loeffler tells how the aeroplane is helping solve the problem of providing medical aid to distant settlers in that country. A single doctor at Darwin has a practice extending over an area ten times that of Great Britain, but the condition of roads and the absence of bridges no longer prevent him from reaching patients far off in the Bush. The Australian Inland Mission, which has already been instrumental in supplying nursing homes to the "Outer Bush," is now proposing to extend its activities to supplying doctors by aeroplane. It has therefore mapped the central part of the continent into circular districts, each with a radius of two hundred miles which could be covered by flying doctors when necessary. As a first step, the Mission proposes to develop a wireless service and to educate bushmen in its use. Meanwhile the aeroplane plan has been submitted to the National Commission on Health, and it is hoped that it will meet with this body's approval. The plan includes utilization of the regular mail aeroplane services to furnish personnel and equipment, under contract, for carrying these flying doctors.

In England communications are so rapid and distances so short that little use has been made of aeroplanes for medical purposes in civil life; but in the United States, if ordinary means of transport fail, the Red Cross can call on the aeroplanes of the Army, the Navy, and the Postal Services to send help to the victims of distant railway accidents, mine explosions, and epidemics. Outbreaks of diphtheria in remote districts have been dealt with effectually by sending doctors, nurses, and serum in a few hours instead of days. Aviation has also helped in the prevention of disease; for in Louisiana aeroplanes have been used to destroy mosquito larvæ by spreading Paris green over the surface of large lakes. All over the world there are rescues and reliefs recorded which recall adventures told by writers in boys' books which seemed fantastic two or three decades ago. In Switzerland an aviator dropped food down to a party cut off on a mountain side; in Sweden some fishermen were saved from starving on an island when their communications were cut off by the breaking of an ice bridge; in Nigeria the wife of a British official was bitten by a mad dog and—by courtesy of the Governor of French West Africa, who sent her an aeroplane—was transported 1300 miles to the Pasteur Institute at Dakar, which she could not otherwise have reached for a month. The aeroplane, it is evident, has its record of salvation as well as of destruction, and in the face of so rapid an advance it is not surprising to learn that in Colombia (South America) a hospital is being built with a flat roof on which, it is hoped, the regular air ambulances will alight with their cargo.—*Lancet*, April 17, 1926.

Pittsburgh Plans Hospital and University Merger.—Plans have been made for a consolidation of the Presbyterian Hospital of Pittsburgh with the medical school of the University of Pittsburgh, involving the erection of a $4,000,000 hospital on property adjoining the new Children's Hospital on Fifth Avenue, according to the *National Board Bulletin*.

The new hospital will have the same relationship with the University as the Presbyterian Hospital of New York bears to Columbia University, with the University directors nominating the hospital staff. The property for the new structure is given the hospital by the University, the site being known as the Kirk Porter property. The hospital will retain its present affiliations, and the consolidation involves few changes in its established plans. The proposed building will provide accommodations for more than six hundred patients.

Village Doctors More Numerous But Work Harder Than City Colleagues.—Village communities have only about two thirds as many physicians in proportion to the number of inhabitants as have medium sized cities, according to figures just made public by the Institute of Social and Religious Research, New York, in a report by Dr. C. Luther Fry, in which are presented the results of an interpretative study of previously unpublished 1920 census data for 177 agricultural villages selected to be as being as nearly representative as possible of the entire United States.

But the villages themselves, as distinguished from the "village communities," have proportionately more physicians than the cities have. The Institute's computations for the different regions show that per 1,000 inhabitants the Middle Atlantic villages have 2.9 physicians and the cities 1.6, the Middle West villages 2.8 physicians and the cities 2.2, and the Southern villages 3.6 and the cities 2.1, while the Far West villages have 2.8 physicians and the cities 2. per thousand inhabitants.

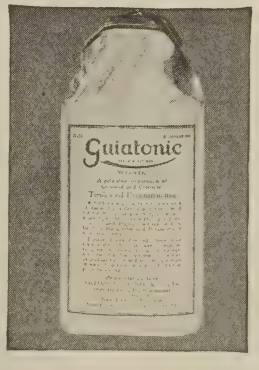
Imperfect or Incomplete Convalescence

as authoritative investigations have recently shown, is responsible for a large part of human illness.

After the fury of an acute infection subsides, the most effective measures are essential, therefore, to make recovery complete and certain. In the use of Guiatonic the practitioner has at his command a most efficient means of aiding and reinforcing the recuperative forces of the body. As a result of its regular use, the patient soon shows a substantial gain in weight, strength and vitality, with an early restoration of that state of physiologic balance that constitutes true recovery.



Guiatonic

A palatable preparation of guaiacol and creosote which may be freely given to the weakest patient, without fear of gastric disturbance. *It contains no narcotics.*

Indicated in all depressed or debilitated conditions, or whenever a tonic is required.

A liberal supply for testing free to physicians. William R. Warner & Company, Inc., Manufacturing Pharmaceutists since 1856. 113-123 West 18th Street, New York City.

"Of course, the large villages have more physicians than the small centres have," says the report, "but the increase does not keep pace with growth of village population, with the result that the proportionate number of doctors decreases as the villages become larger.

"These figures do not mean, however, that villages have a larger number of doctors in proportion to the population they serve. It is a known fact that village physicians serve open country inhabitants as well as villagers. The first hand studies of the Institute's field workers found that almost no doctors live in the open country areas adjacent to villages. Open country inhabitants are therefore compelled to turn to villages when they want medical attention.

"In every region the cities have from one third more to nearly twice as many doctors as have 'village communities.' These differences are all the more significant because the distance a village doctor must travel in visiting many of his rural patients makes it difficult for him to care for as many people as can a city doctor."

Clinical Calorimetry; Infection and the Ketogenic Balance.—Henry B. Richardson and Samuel Z. Levine (*Journal of Biological Chemistry,* March, 1925) determined the ketogenic balance in relation to the excretion of the acetone bodies in four patients, two diabetics and the other two not. All these patients were suffering from infection. These infected patients failed to excrete more acetone bodies for a given fatty acid-glucose ratio than did the noninfected individuals previously studied. The evidence from the data presented is that the ill effects of infection in diabetes are due, not to a disturbance in the ketogenic balance, but to an actual reduction in the amount or proportion of glucose oxidized.

The Rôle Played by Physicians in the Discovery of the New World.—In an interesting article published in the *Boston Medical and Surgical Journal,* March 18, 1926, Dr. William Pearce Coues said that the important part played by physicians in Columbus's great discovery was not generally realized.

La Chronique Medicale for December, 1922, he said, had an interesting article on this subject. It seemed certain by documentary evidence that it was largely due to the intelligence and perspicacity of a Spanish provincial physician, that Columbus was able to go forth in search of the new world, instead of being confined in the awful captivity of the times, as a person of unsound mind. The account of this important incident in the life of Columbus was given, which, translated, reads as follows:

"Another physician who played an important part in the life of Columbus was a simple village doctor, exercising his craft at Palos de Morguen in Andalusia. Columbus, tired out and ill had sought refuge in the convent of Santa-Maria de la Rabia. The Abbé in charge of the convent, thinking his guest was insane" (on account of his strange talk of new continents sand expeditions), "summoned Dr. Garcia Fernandez to attend the sick man.

"This wise physician, is discoursing with the illustrious explorer on geography and astronomy, quickly found that he did not have to do with an insane person, but with a man of great genius. He told his

opinion to the Abbé, and the knowledge of this humble but learned physician probably saved Columbus from a miserable fate."

"Garcia Fernandez started with Vincent Yaneth for the discovery of the Orinoco, and was the first to sound its waters, from whose shores there was furnished later so much of therapeutic value."

"It must be remembered that it was a Florentine physician, Toscanelli, who fortified Columbus in his conviction of the existence of a great unknown continent. Without Toscanelli's advice, Columbus would have steered in a direction which, instead of leading him to America, would have led his vessels away from it.

"Two physicians accompanied Columbus in his first voyage, both unhesitatingly abandoning country, family and ease, to take part in the expedition organized by the great navigator. One of these physicians was 'Maitre Alonzo,' on board the Santa Maria and the other 'Maitre Jean,' on board the Pinta. Alonzo returned to Spain with the admiral, and they were overtaken by a frightful storm. The physician accompanied Columbus to Seville and Barcelona, but it is not now possible to say whether the return was by sea or by land. Maitre Jean finished his days in a tragic manner, being horribly massacred by the Indians, the first martyr of our profession in the new world."

"The chief physician of the second expedition, comprising 1,500 men, is better known to us. Dr. Diego Alvarez Chanca, of Seville, was physician in ordinary to King Ferdinand and Queen Isabella. His determination to accompany Columbus on his voyage was met with approbation by their Majesties, who addressed the following letter to him:

"The King and the Queen to Dr. Chanca: We have known that in your intention of serving Us, you wish to go to the Indies, and in doing this you will serve Us. You will be of help to those who go there by our orders, for our service: do this and go with our Admiral to the aforesaid Indies, he will talk to you of what will concern your sojourn there. . . . We send you a letter, so that you will be in receipt of the salary and emoluments that you usually receive from Us."

"Speaking of this physician in a letter to King Ferdinand, Columbus says, 'I have to inform Your Royal Highness of the constant labors of Dr. Chanca, on account of the great numbers of the sick he attended, and his occupation about our stores. He has given proof of the greatest zeal in all that concerns his art. Your Royal Highness, having left me at liberty to fix the sum of the honorariums which I am to give him, . . . I have established for him an annual credit of fifty thousand maravedi.' We are told that Dr. Chanca saved the life of Columbus, when he was attacked by a long continued fever, and that this physician wrote the first accounts of the new world, in the form of a report, addressed to the Municipal Council of Seville. He was the author of a number of books."

The article concludes, "That it is not probable that Dr. Chanca was the only physician who accompanied Columbus on his second voyage. It is likely that another surgeon made the voyage with the admiral, although history is mute concerning his name. His presence in this second expedition is incontestable, if we believe the manuscripts that we are entitled to believe. It is indeed probable that there were a number of physicians and surgeons, who passed over to America with an expedition numbering so many men."

More definite facts concerning this question will probably never be known, Dr. Coues said, but it must be of unfailing interest to physicians of the present, the world over, to realize what an important part those of their profession played in the discovery of the New World.

Health of New York.—The *Public Health Committee Report* of the New York Academy of Medicine for the year 1924 was published a short time ago. It is a document of surpassing importance and interest and its statements and views show the value of preventive measures. Child welfare has made much progress in New York city but is still susceptible of far greater advance. It is pointed out that among the principal problems before the community in this field are a better coordination of effort on the part of the various agencies; a more thorough understanding of the relative importance of the several activities; selfanalysis of the work by the operating agencies; and a research agency to evaluate the results of work done and to make available the results of the numerous studies, demonstrations, and experiments which are carried on in various parts of the country.

Stress is laid upon the fact that although there is a marked increase in the use of prenatal clinics and baby health stations, and while the indication is that at least twenty-five per cent. of the babies of New York come in contact with health stations, there exists no adequate machinery for effective work with the pre-school child. This lack of organization bears a sinister aspect when it is borne in mind that the greatest incidence of some of the most important diseases of infancy occurs in the age period under five.

Medical inspection of school children also needs reorganization and provision for neuromental examination of children, reduction of malnutrition, correction of dental defects and better organization of fresh air work are some of the links in the chain of child health activities which require strengthening. Attention is directed to that most common defect of children, that of bad teeth, and it is stated that the communal provision for dental care and prophylactic treatment of children in New York is insufficient to supply the demands for proper oral hygiene. The importance of teeth in the health economy of the individual is obvious and the fact that according to reports of the City Department of Health, sixty-two per cent. of the children have defective teeth, and a relatively small percentage have these defects remedied, are matters which make it imperative that energetic steps be taken on the part of all concerned toward a comprehensive program in oral hygiene. As the report goes on to say, the school clinics afford an effective means of combating the existing evil of neglected teeth through the prophylactic and curative work done as well as through education.

By proper supervision children whose parents can afford to pay for dental care could be eliminated from

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

the clinics and urged to obtain the necessary services outside. It is noticed especially in the Report that accidents causing death and crippling, as well as minor injuries, are annually increasing both in actual numbers and in relative importance. The automobile is the greatest offender in this respect. Statistics of highway accidents in New York city from the Police Department records show that the total vehicular accidents in three years from 1921 to 1923 increased from 26,890 to 32,885, or 22.3 per cent., and according to the State Department of Health the mortality rate from automobile accidents in the State rose from 10.2 in 1917 to 15.9 in 1923. Moreover, a table prepared by the National Bureau of Casualty and Surety Underwriters and published by the Metropolitan Life Insurance Company indicates that in some cities the hazard from automobile accidents is several times greater than in others as measured by death rates to the one thousand automobiles registered.

New York city stands next to the highest in the rate of life destruction. Another question of interest considered by the Committee was that of drug addiction. According to the study made by Kolb and Du Mez, published in the May 23, 1924, issue of the *United States Public Health Reports,* the number of addicts in the United States has decreased steadily since 1900 and that the maximum number in the country at the present time is estimated at one hundred and fifty thousand.

A problem which is occupying the attention of thinking people in all the civilized countries of the world, namely the proper care of socalled chronic cases, is discussed in the Report. The situation in New York city at the present time is confessedly unsatisfactory. There are very few institutions where proper care is given, and there is no differentiation made between patients requiring merely custodial care and those who would be benefited by specialized medical and nursing care. Of course, there are many who require special care and in many instances special treatment. In particular may be mentioned those suffering from the various forms of rheumatism with the frequently related cardiac and vascular troubles. Institutions for this class of patients are few and far between in New York city and are for the most part unsatisfactory. They were established chiefly for the incurable and what is urgently needed are hospitals for the care of those who have not yet advanced to the hopeless stage. As said before the report is an extremely valuable presentation of the existing situation in New York city as regards the public health together with suggestions for further conserving and maintaining at a high level the health of the community.

There are many means whereby disease or ill health may be prevented and the health of the masses improved. In its report the committee of the New York Academy of Medicine does not deal with the greatest cause of disease, at any rate, in cities, namely housing and environment.

The housing question is outside the scope of its discussions and inquiries, but it may be again emphasized in these columns as it has been emphasized previously that if the slums of cities could be cleared away, and the children reared in an environment to which light and air had free access, disease and invalidity would be far less common and mentally and physically the race would be vastly improved. Personal and domestic hygiene should do as much or more for the conquest of disease during the next few years as public health measures have done during the past few years.

Bronchoscopy in Disease.—Chevalier Jackson (*British Medical Journal,* October 17, 1925) states that in any case of suppurative focus communicating with a bronchus, and in which the surgeon and the internist deem external operation not strongly indicated, bronchoscopic aspiration should be used to supplement medical care. A very satisfactory percentage of such cases will be cured. The chief contraindications to bronchoscopy are, 1, a moribund condition of the patient, and, 2, imminent rupture of the focus into the pleura.

Suppurative foci not communicating with a bronchus can be penetrated with the bronchoscope if deemed advisable, but the wisdom of doing so has not yet been demonstrated. If for any reason the surgeon deems external operation inadvisable, bronchoscopic penetration may be considered. In such cases spontaneous rupture into the bronchus or the pleura usually occurs sooner or later, and delay in external operation is very rarely advisable.

During the Summer Months the question of what measures to employ to restore —and maintain—the nutritional balance, is often a difficult one. The digestive and assimilative functions tend to become inactive, and the natural trend of the body is toward loss of vitality and weight.

At this season—and under these conditions

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

has proven an ideal supportive and reconstructive.

Especially is Gray's Glycerine Tonic Comp. a satisfactory ***succedaneum*** for cod liver oil, or other products apt to place an extra tax on the digestion, for it aids rather than burdens the digestive organs, and increases rather than lowers the appetite and intake of food.

One of the main reasons, therefore, why so many physicians have come to use and highly appreciate Gray's Glycerine Tonic Comp. is that they have found it can be administered as freely in the Summer as at any other time of the year in the treatment of their convalescent, debilitated and elderly patients.

Miscellany.

Rheumatic Diseases and Heart Disease.—That group of diseases and conditions of ill health loosely massed together under the term rheumatism are in themselves crippling and fatal but their deadliness comes chiefly from their sequelæ and especially from their malinfluence on the heart. Diseases of the heart in one form or another are responsible for the greatest number of deaths in most civilized countries due to one cause only. Moreover, it has been shown with striking clearness that rheumatism in some of its protean manifestations is the main factor in bringing about heart disease.

While rheumatism is quite rife in this country, it is in Great Britain that it is most prevalent and is permitted the widest scope for taking its toll of life and wreaking its damage on the body. The word permitted is used advisedly as rheumatism is largely a preventable disease. Another reason why rheumatism should be fought with all the vigor at our command is because it so greatly affects the manual worker that it may be justly classed as the outstanding industrial disease and is a menace to prosperity viewed from its economical aspect.

One sixth or thereabouts of the industrial invalidity of Great Britain is owing to that group of diseases commonly known as "rheumatics." The figures for this country are not available but there is little doubt that rheumatism and its after effects are responsible for great deal of the industrial invalidity here. Acute rheumatism is that form which most directly interferes with the smooth working of the heart machinery and its worst effects are exercised on children. Again acute rheumatism, as is the case with acute pneumonia and differing from most acute specific fevers, entails the liability to recurrence rather than immunity and the recurrent attacks are more apt to injure the heart permanently than the first attack. Believing then that in rheumatism, and in so far as the young are concerned in acute rheumatism, lies the main initial and exciting causes of endocarditis and other deviations from the normal course of the heart's action, the object is to prevent the occurrence of the malady and particularly, perhaps, that of the acute form. This last form is now generally held to be specific, although the micrococcus discovered by Dr. Poynton and Dr. Payne is doubted by many to be the true cause.

It seems, therefore, that in the prevention of acute rheumatism, every effort should be made to discover its origin or origins. Both children and adults after an attack should have rest and prolonged convalescence in order to prevent recurrence and subsequent heart trouble. It has been computed by some authori-

PYRAMIDON

As an analgesic Pyramidon has alleviated pain in many conditions for 30 years. Today it is employed more extensively than ever before.

Headaches and dysmenorrhea submit readily to Pyramidon. Gratifying results are obtained also in neuralgia, articular and muscular rheumatism, neuritis, sciatica and other painful affections.

By the use of Pyramidon objectionable opiates may frequently be avoided. Pyramidon is free from by-effects to a marked degree. It does not produce somnolence.

The convenient 5-grain tablet usually yields favorable results. Should discomfort recur after 3 or 4 hours the dose is repeated.

ties here that such homes are required in a proportion to one bed to every ten thousand persons in the larger cities. Also it would be a long step in advance if there were special hospitals for acute rheumatic cases with cardiological and pathological departments.

The condition of the tonsils and the mouth should be scrutinized closely and defects and deficiencies remedied as far as is possible because tonsillar and oral sepsis, including teeth and gums, appear to be important etiological factors in the causation. Such scrutiny, of course, is especially applicable to children. Indeed diminution of acute rheumatism and of sequential organic heart disease, may be regarded as one of the main aims of school medical service. Lambert has shown that the number of in-patients under fifteen years of age admitted to Bellevue Hospital with acute rheumatism has not diminished, but that the great diminution in the total number of patients with the disease has been due to the diminished number of older persons, especially those between twenty and twenty-nine years of age, thus demonstrating the value of school examination and treatment.

Recent American statistics have shown that tonsillitis causes a large amount of industrial invalidity, necessitating sick benefit. Another point in connection with acute rheumatism, to overlook which would be careless, is the influence of environment. It may be stated almost positively, that damp, dark illventilated dwellings are favorable to the inception and spread of all forms of rheumatism and that the traditional association of houses with all varieties of rheumatism probably, rests on a substantial basis. Consequently, the abolition of slums and of basement dwellings, diminution of overcrowding, the increase of sunlight and ventilation and the more general adoption of house building of antidamp precautions, would doubtless aid in lessening the incidence of rheumatism.

While acute rheumatism is usually looked upon as a specific disease, chronic joint affections, the form which may be rightly termed the industrial disease, are for the most part probably of a toxic origin, that is to say, for instance, in perhaps one third or even one half of the cases coming under the head of rheumatoid arthritis there are the strongest grounds for holding that there is a definite focus of septic infection, and in the cases of osteoarthritis the proportion may be assumed to be higher. Undoubtedly in many instances chronic rheumatic diseases can be largely prevented by suitable manner of living and especially by careful diet and avoidance of prolonged constipation.

It seems reasonable to suppose that by maintaining free elimination and excretion the toxic material

which otherwise is apt to collect and establish itself in the system is kept away and rheumatism is discouraged from developing, the soil not being favorable. Hereditary predisposition or diathesis is another factor which is beginning to be again taken into serious consideration when discussing the causes of rheumatism. In some individuals the soil may have been prepared by their progenitors for the ready reception of certain forms of rheumatism.

In the treatment of chronic rheumatic diseases as of acute rheumatism much good may be effected by special measures or rather by the establishment of special institutions with special equipment and with special staff. The treatment of arthritic patients in the most scientific and effective manner is impossible either by the general practitioner or by the ordinary hospital. A special institution is really economical in the long run because large sums are being lost yearly in allowing these diseases to progress practically unchecked. And in addition the concentration of such patients in an institution thoroughly equipped for the purpose of research must greatly increase our knowledge of the disease. Treatment of severe arthritis which while though now quiescent has resulted in severe crippling from contractures of knees or at other joints, is sometimes treated by forcible extension and the use of splints.

Dr. F. J. Poynton, the well known British authority, introduced on March 24th last a discussion on rheumatism at the Hunterian Society, London, in which he pointed out that he had witnessed some very successful results from the use of forcible extension and splints by Mr. Hoefftcke of London, the originator of the method. It is encouraging to know that interest is being aroused in this the most crippling disease of industry and in its effects on the heart the most deadly disease of civilization. The group of diseases known as rheumatism are in their ramifications most difficult and obscure and it seems that the suggestion that there should be special institutions for the observation of both acute and chronic cases and in reference to their effects on the heart in particular, are guided by sound common sense. The epidemic diseases have been and are being routed and ousted and it is time that campaigns were inaugurated against the chronic diseases which are steadily and in some instances rapidly increasing.

During the Summer Months the question of what measures to employ to restore —and maintain—the nutritional balance, is often a difficult one. The digestive and assimilative functions tend to become inactive, and the natural trend of the body is toward loss of vitality and weight.

At this season—and under these conditions

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

has proven an ideal supportive and reconstructive.

Especially is Gray's Glycerine Tonic Comp. a satisfactory ***succedaneum*** for cod liver oil, or other products apt to place an extra tax on the digestion, for it aids rather than burdens the digestive organs, and increases rather than lowers the appetite and intake of food.

One of the main reasons, therefore, why so many physicians have come to use and highly appreciate Gray's Glycerine Tonic Comp. is that they have found it can be administered as freely in the Summer as at any other time of the year in the treatment of their convalescent, debilitated and elderly patients.

Mortality Record of the First Six Months of 1926.—Health conditions among the wage earning populations of the United States and Canada during the first half of 1926 were not only less favorable than for the same period of last year but of any year since 1920. The increased mortality in the first six months of 1926 was due, for the most part, to above average prevalence of influenza and pneumonia. It will be recalled that in 1920 the country experienced a very severe recrudescence of the 1918 influenza pandemic resulting in a very unfavorable death rate during the early part of that year. But in the latter half of 1920, the health situation took a surprising turn for the better; and when the year had run its course, it was found that the mortality of the industrial population had actually registered the minimum rate, up to that time. General population mortality statistics likewise showed that, with a single exception, 1920 had registered a lower death rate than any previous year. What occurred in the second half of 1920 suggests strongly that the 1926 influenza flurry constitutes, in itself, no real ground for pessimism as to the final health record for this year. It is still entirely possible that sufficient improvement will develop in the latter half of 1926 to counterbalance the high rate of the first half of the year. Up to July 10, the cumulative death rate of 1926 was only four per cent. above that for the corresponding period of 1925.

In addition to the higher rates for influenza and pneumonia, alcoholism numbered 598, corresponding to a death rate of 6.9 per 100,000, as compared with a rate of 6.7 for the corresponding period of 1925. In the first half of 1924 the rate was 6.0.

Since January 1, 1922, a period of four and one half years, alcoholism has caused 1,965 deaths among Metropolitan Industrial policyholders. Of these deaths, 1,943 occurred among approximately 16,000,000 persons living in the United States, while only twenty-two were recorded among approximately 1,000,000 Canadian policyholders. Most of the few deaths from alcoholism among Canadians insured in the Metropolitan Industrial department, during recent years, have occurred among approximately 360,000 policyholders in the Province of Ontario.

Deaths from wood and denatured alcohol poisoning numbered 10 during the six months' period. During the same months of 1925 and 1924, there were 15 and 8 deaths respectively. Deaths from this form of acute poisoning are unquestionably less frequent than they were in 1920 and 1921. Prior to these years, however, it was a comparatively rare occurrence to have a death reported from this cause.

A check of the Metropolitan's mortality records, by quarters, over a long series of years, shows that the mortality from alcoholism has a seasonal incidence. Although this is not very pronounced, it is nevertheless a fact that more deaths, on the average, occur during the first quarter of the year than in any of the other three months' periods.

Suicides have been more numerous this year and homicides a little less frequent. Accidental drownings have also registered a lower death rate.

The record of the half year for automobile fatalities is bad. The rate has increased among both white and colored policyholders, particularly the latter. It is true that among the whites the increase as compared with last year is not large (four and one half per cent.); but the fact remains that an increase has again been recorded. Even a stationary rate for automobile fatalities would be a challenge to every organization interested in public safety problems.—*Statistical Bulletin Metropolitan Life Ins. Co.*

Midwifery.—W. A. Daley, M.D., Hull, stated in considering the future midwifery in the homes of the people we must consider first what are the prevailing tendencies with regard to midwifery in this country. It appears to me that they are:

The percentage of women delivered by midwives is increasing and that of women delivered by doctors is decreasing.

The medical man is now, at all events in the industrial areas, attending a very small proportion of normal cases.

The need for antenatal supervision and even examination is being recognized increasingly; routine examinations of the urine, and clinical examination to ascertain disproportion, if any, between the head of the fetus and the mother's pelvis will, in a few years, become matters of routine.

The number of women who desire to enter a maternity hospital, maternity home, or nursing home, either public or private, for their confinement is increasing.

The number of confinements which take place at home is therefore decreasing, but the proportion attended by midwives is increasing, and the duty of providing midwifery in the home is much more exacting than it was some years ago.

Despite the increasing tendency to enter an institution for the confinement, there are still very many confinements which must take place at home because of inability to make proper provision for the care of the other children while the mother is away from home, and because some women have an inherent dislike to entering any institution. There will, therefore, always be sufficient work to provide a living for a large number of midwives who desire to work in the home of the people, but we want to improve the standard of midwifery done there. Between one thousand and two thousand preventable maternal deaths still take place in this country every year, and thousands of cases of chronic illhealth result from bad midwifery. Our future needs include better training of the doctor in midwifery, and better training of the midwife. It must be recognized that the time has gone when midwifery should be regarded as a method by which a policeman's or a postman's wife can augment her husband's earnings. The practice of midwifery should be similar to the practice of ordinary medical or surgical nursing, and the midwife should practice her calling, as does the trained nurse, in institutions or from nursing homes, and only occasionally from private houses. Incidentally, this would make the lot of the midwife much easier than it is at present, because I envisage the time when three or four midwives, who practice in the homes of the people, will join forces and live together; in this way they will be able to arrange definite offduty times. The most important immediate need is to encourage practising midwives to

take an interest in antenatal work, and to assist them in every possible way to improve their technical knowledge.

In one town where I worked I succeeded in persuading a large number of midwives to undertake definite antenatal care for each of their patients by providing certificates, which could be used for professional advertisement, to all who kept an antenatal register provided by the local authority, in which was set out questions which the midwives should ask each of their patients, and the answers to each, recorded in the register, indicated at a glance whether or not the case was likely to be normal. The midwives were required to examine specimens of urine, or to send them to the antenatal clinic for examination at definite intervals. In this way patients as well as midwives began to appreciate the value of antenatal work, and once the patients realize the need for antenatal work, the battle is won.

Every local supervising authority under the midwives act should provide lectures to the practising midwives. The lecturers should emphasize the fact that in the avoidance of obstetrical disasters, method is much more important than environment, and that good midwifery can be done if the method is good, in surroundings which are the reverse of those found in a well conducted hospital.

The most important point to be considered in endeavoring to improve midwifery in the homes, and I make the strongest possible plea for it, is the collaboration and goodwill of all concerned, namely, the private midwife, the private doctor and the local authority's medical and nursing staff, including the staff of the antenatal clinics and maternity homes. We must try to link up the midwives with our municipal schemes for preventing maternal deaths, but we must act as educators and not as detectives. There must be mutual understanding on both sides. The midwife must realize that it is not to her advantage to have a death either of mother or child among any of her cases, and she must realize, too, that it is not the object of the local authority to attract to maternity homes women who have already booked a private midwife, unless there is some real medical reason why the confinement should be conducted in an institution. Private midwives should be encouraged to cooperate in every way with the staff of the antenatal clinic. If they send a patient there, the doctor should always write to the midwife giving her the result of the examination, and the reason for any recommendation which is made. Midwives should be encouraged to attend the antenatal clinics with their patients. It is obvious that with the increased duties, there should be increased pay for the midwives.

The standard of knowledge and practice of the private midwife is improving every year. If the private midwife will only cooperate heartily with the municipal authorities, I am quite sure that hundreds of lives of mothers and children will be saved every year.

peral state. Public and private agencies have endeavored to provide instruction and supervision for pregnant women, increasingly stringent regulations of midwifery have been instituted, hospital service in confinement has been much improved and made widely available, and postnatal care has been provided through public health nursing agencies working in the home. It is of interest, therefore, to examine the Census Bureau's records of the mortality from abnormalities associated with childbearing for an area of the United States where much of the admitted improvement in maternity service has taken place during the past ten years.

There seems to have been a slight increase in the death rate for puerperal conditions reckoned against births in a constant area. This is clear from a comparison of the rates for the two periods 1915-1917 and 1921-1923. The death rates for puerperal sepsis and puerperal eclampsia have remained unchanged. These two conditions account for more than one half of the mortality connected with childbearing. Most of the preventive effort of agencies for maternal care has been directed at these two conditions.

Some improvement in the mortality figures has been observed in rural districts of these nine states. But here we have to consider the effect of improvement in birth registration. An increase in the proportion of births registered would tend to decrease puerperal mortality rates based upon births.

The fact that there has been no significant improvement in material mortality rates during the period under review should provoke inquiry. What could have been expected of the maternity work which was instituted with such fervor and zeal ten years ago? Was it founded upon sound principles, were its aims realizable, and was there a programme sufficiently comprehensive to affect the vast number of maternity cases which occur annually in the area under survey? Or have new factors intervened to offset the work of boards of health and of private agencies? Has the increased proportion of hospitalized cases been accompanied by more septic complications? Whatever be the answers to these and other questions which arise, it is clear that over the past decade little if any impression seems to have been made upon the risk of death in childbearing.—*Statistical Bulletin Metropolitan Life Insurance Co.*

Unity of Effort in the Child Welfare Service.—There are few voluntary organizations today who do not proclaim coordination of policy and cooperation of effort as their guiding principles. Local authorities also, who in the past have been slow to acknowledge outside endeavor, are at length admitting the soundness of these doctrines, while of recent years the State has constantly urged their primary importance, not only in promoting efficiency, but in establishing economic administration. Nevertheless, in the experience of every unprejudiced worker these doctrines, while loudly commended in theory, are still far from commanding full allegiance. Universal activity and widespread enthusiasm prevail on behalf of the child, but these fall short of their goal for lack of that consolidated purpose and intelligent direction which would not only incalculably increase the benefits achieved, but would equally increase the purchasing power of funds expended. Wider development and more substantial achievement in child welfare work are possible in many areas without any additional expenditure through the more intelligent development of existing machinery and the fuller coordination of existing endeavor.

This all essential unity and coordination can only be established when the policy of the three chief services of the State, local endeavor, and voluntary enterprise is so wisely directed as to meet by a combined effort the manifold needs of the child, eliminating the waste constituted by overlapping effort, and avoiding the loss entailed by incomplete or inadequate service.

POWER OF THE STATE

At the outset it is essential that intelligent workers in every area, whether responsible members of the local authority or pioneers of voluntary enterprise, should acquaint themselves with all legislation on behalf of the child and thus know the full responsibility accepted by the State for the child's wellbeing.

Since the establishment of the school medical service in 1917 down to the present time, the State has encouraged and promoted child welfare work by a series of progressive enactments which give to local authorities very extensive powers to initiate and carry out schemes for the protection and help of the children in their areas. But the State can only promote and develop such legislation as the people demand. Further legislation is dependent upon the will of the people urged through individual pioneers, and carried into law by the elected representatives who form the government of the nation.

Here we have a ground for common policy and mutual endeavor between the state and all other child welfare workers, whether official or voluntary, throughout the country.

It is clear that workers in various localities, particularly members of local councils, must cooperate with the State by putting into action all the powers which legislation gives. They must continually strengthen the hands of those who frame and those who administer laws by proclaiming the beneficial results accruing from new enactments. They must press for the provision of such new benefits as they have proved to be essential.

Those who blame the State because legislation is nonoperative in their area or is insufficient for the established needs of that area, fail to realize where the ultimate responsibility in this matter lies. It lies with the local authority, and it lies always and finally with the individual. Reforms throughout history have been the outcome of the proved experience of a few devoted workers whose influence has extended throughout the locality, and has gradually created such a volume of public opinion that the voice of the few has become the voice of the many, and the benefits promoted in a small area for a limited section of the people have extended to the nation as a whole. The extent of the State's power to benefit the child depends upon the cooperation of the local authority in carrying out legislation, and the demand of the people for that legislation.

RESPONSIBILITY OF THE LOCAL AUTHORITY

Upon the local authority and voluntary endeavor therefore devolve heavy responsibilities for the wellbeing of the children in their areas. If these children

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

are diseased, crippled, or neglected, it is for the local authority to put into action all power given them by the State to remedy these conditions. It is for individual voluntary effort to support the local authority in such action, to supplement in every possible manner their endeavor, and by wellplanned propaganda to create the public opinion necessary for further progress. Such determined and united endeavor rarely fails to attain the goal.

But the principle that union is strength must be carried further. The local authority must fully coordinate the various departments of its child welfare scheme, and the manifold endeavors of voluntary effort must be similarly united. These two services must throughout work together, complementing and supplementing each other so that any required need of the child shall be fulfilled by that organization, whether official or voluntary, which is best fitted to fulfil that need, or by a joint endeavor so completely united as to form a continuous effort. The child must be throughout the first consideration, not the organization, still less the units making up the organization.

We have heard of the permanent damage sustained by the children of the nation by rheumatism contracted during school years or earlier. Mr. Girdlestone has urged the necessity for more scientific and more closely coordinated endeavor on behalf of children crippled by surgical tuberculosis, by paralysis, and by rickets. Papers like these should be read and assimilated by every member of the public health, the infant welfare, and the school medical service, and should also be studied by all voluntary organizations.

VOLUNTARY ENTERPRISE AS THE COORDINATING BODY

Tuberculosis is preventible, rickets is preventible, paralysis will soon be within the realm of preventive medicine. If these diseases are preventible, where is the leakage? The leakage is to be found in incomplete infant welfare work, in incomplete medical service, in the lack of adequate hospital organization (beds in some cases, but mainly organization), in the almost complete absence of good aftercare and followup work, in the gaps between the infant welfare work and the school medical service, in the failure to educate the mother and to make it possible for her to give that care and training to the child which is her prerogative, in the failure to educate the teacher to recognize those early symptoms of disease which call for the assistance of the school medical service or of voluntary agencies. Much of the effort of the local authority and of voluntary enterprise is characterized by lack of appreciation of the breadth of this greatest and most important of all fields of social service, and of the absolutely essential importance of comradeship in work. How many municipal committees work in watertight compartments with no vision of that ultimate goal of all endeavor, the selfsupporting, healthy, happy, citizen?

The committee for the feeding of necessitous school children rarely realizes that the problem of the hungry child does not happily arise in this country at this time. What does arise is the problem of the illnourished child, and for this the school meals committee needs the assistance of the school medical committee. The committee in charge of the physically defective schools fails to recognize that the roots of its endeavor lie with the school medical service and with the infant welfare service.

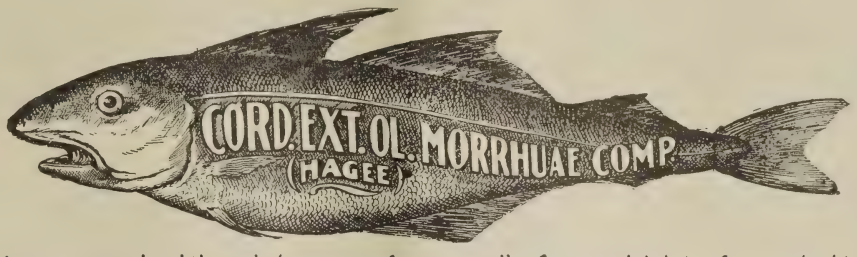
There are here and there local authorities who have established unity of endeavor both by coordinating their own effort and by making the fullest use of voluntary organizations, but such authorities are still in the minority. Many are content to do as little as they can and have an extraordinarily limited outlook on the whole problem. Many are antagonistic to voluntary enterprise and will not see the incompleteness of their own endeavors without its aid. On the other hand there are still many members of education authorities who are prejudiced against what is regarded by them as the noneducational part of their work. This prejudice has its origin in the financial problem, but it must nevertheless be overcome. It is impossible to separate the mental development of the child from its physical fitness. The Board of Education laid down this elementary truth long ago, but it is another of those principles to which many only give lip service.

The school medical service should be the centre round which all child welfare activities are grouped until the time comes when its place is usurped by the maternity and infant welfare workers. Care committees should be established in connection with all large elementary schools, and through these committees the fullest use should be made of all efficient voluntary organizations. Where care committees are not established the school medical service should deal with the voluntary organizations direct. Voluntary enterprise forms the link with the child's home. It is clearly impossible to help a child adequately without knowledge of the environment in which the child lives, the surroundings of the home, the degree of poverty in the home, the family medical history, what leisure the mother has to care for her children, her knowledge of hygiene and food values, and those many limitations in the child's environment which so materially reduce its chance of wellbeing.

The records of the infant welfare worker should be available for all children entering school, and when the infant welfare worker's supervision ceases at the age of three some provision should be made for the toddler. If such records are available and are carefully used, and voluntary aid is equally available, it will be possible to ensure that from the early days of school life illnourished children are fed, or that nutrition is secured by such food substitutes as cod-liver oil, malt, etc., that the children living in crowded areas and who are below the standard of health have the benefit of fresh air funds and convalescent homes, and that children attending hospitals are adequately followed up and their needs provided, and that the school doctor and hospital doctor work together. This unity of endeavor between the school doctor and the hospital doctor is nowhere more essential than in the schools for physically defective children. In securing this the aid of voluntary coordinating organizations, such as the I. C. A. A. Child Welfare Association, is invaluable, and these organizations secure the equally essential cooperation in the home. All workers for the crippled child, always including local councillors, must have the right understanding of the problem it is their privilege to be called upon to solve. Their task is to make crippled children a

COD LIVER OIL IN TERTIARY SYPHILIS

has such distinctive value in building up and charging the tissues with resistance that its use should be an important part of every case's therapeutic management. The patient under its reconstructive influence makes a better response to specific treatment.



owing to its palatability which permits of an unusually free availability of its up-building properties, may be chosen for use in these cases with every assurance that it will be well tolerated and fully serve its purpose.

Cord. Ext Ol. Morrhuae Comp. (Hagee), therapeutically, is all that the plain oil is.

EACH FLUID OUNCE OF HAGEE'S CORDIAL OF THE EXTRACT OF COD LIVER OIL COMPOUND CONTAINS THE EXTRACT OBTAINABLE FROM ONE-THIRD FLUID OUNCE OF COD LIVER OIL, (THE FATTY PORTION BEING ELIMINATED), FOUR GRAINS CALCIUM GLYCEROPHOSPHATE, FOUR GRAINS SODIUM GLYCEROPHOSPHATE, ONE HALF GRAIN SALICYLIC ACID, (MADE FROM OIL WINTERGREEN), WITH GLYCERIN AND AROMATICS.

disgrace to any locality, to put all societies for the care of cripples out of a job.

To achieve this goal early ascertainment of crippling disease is essential. Early ascertainment depends upon an efficient medical service, efficient and adequate infant welfare service, efficient and coordinating voluntary service.

It is in the infant clinic that the diseases which produce crippling can be ascertained, and an intelligent infant welfare service will immediately refer children so threatened to the orthopedic clinic.

One word about maternity welfare. Sir George Newman stated in one of his illuminating reports, which are an inspiration, that three thousand women lose their lives in childbirth annually. The damage rate is, of course, very much greater. This constitutes preventible loss. The environment of the child is its mother. What the child fails to get from its mother can never be made up in after years. The working class woman in thousands of homes in this country has no chance of any joy in motherhood, or of becoming a good or even intelligent mother. Unnecessarily impaired health, overwhelming domestic duties, inconvenient sunless houses, no labor saving devices, no leisure, holidays unknown. It is difficult to understand why every man and woman who has had a good mother, whose home has been a sanctuary, does not rise against such conditions in protest in this matter. Here is the biggest and most farreaching menace to the wellbeing of the nation's children.

Last year I visited those wonderful clinics of Dr. Rollier at Leysin. It was a living lesson in the healing power of sunshine and fresh air. When we learn to procure the benefit of this power for the mothers and children of our great cities, when annual migration into the country is possible for those who need it most, we shall quickly empty our hospitals.

One final word on the coordination of voluntary enterprise. I can only just refer to this subject. It is impossible to develop the full values of unity throughout the child welfare service within the limits of this paper: I have to scamp part of the subject. I am speaking tonight on the loss to the child produced by lack of coordination and linking up between our magnificent hospital service and outside social services, and what I have to say, then, will supplement this section of my paper.

I want just to urge here the need for constant safeguarding against overlapping in voluntary work. Many organizations doing work beyond praise in the field for which they were established are guilty of wasteful overlapping endeavor. How many organizations, for instance, develop special holiday or convalescent schemes without any reference to well established and existing activities? Thus the same child often benefits twice in the same year, while hundreds of others get no chance at all. Equally thus the right children are not chosen for the homes or camps where they would get most benefit. Use your experts in all sections of social work.

Such errors in judgment are mostly the result of excess of zeal and lack of knowledge. No earnest worker would be a party to overlapping who stopped to reflect that public support is after all limited in its extent, and that overlapping endeavor in one field diverts funds from fields where effort is badly needed.

The worker in this great and privileged field who pursues personal aim, either for himself of his special organization, is unworthy of his calling. For the welfare of the child is the welfare of the entire nation, and the fruits of our endeavor, if it be faithful, will live to bless our cities long after our little span of existence has ended. Let us, therefore, with a wide vision, with a big heart, and an unconquerable faith, accept our part in this greatest movement of the century, a movement in which men and women of all nations recognize that mankind owes the child the best it has to give, and pledge themselves, their gifts, and their lives to secure this great end.

During the Summer Months the question of what measures to employ to restore —and maintain—the nutritional balance, is often a difficult one. The digestive and assimilative functions tend to become inactive, and the natural trend of the body is toward loss of vitality and weight.

At this season—and under these conditions

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

has proven an ideal supportive and reconstructive.

Especially is Gray's Glycerine Tonic Comp. a satisfactory ***succedaneum*** for cod liver oil, or other products apt to place an extra tax on the digestion, for it aids rather than burdens the digestive organs, and increases rather than lowers the appetite and intake of food.

One of the main reasons, therefore, why so many physicians have come to use and highly appreciate Gray's Glycerine Tonic Comp. is that they have found it can be administered as freely in the Summer as at any other time of the year in the treatment of their convalescent, debilitated and elderly patients.

Valentine's Meat-Juice

In **Typhoid Fever Valentine's Meat-Juice** demonstrates its **Ease** of **Assimilation** and **Power** of **Restoring** and **Strengthening.**

I. Burney Yeo, M. D., *Professor of Therapeutics, King's College, London, in the well known work, "Food in Health and Disease":* "In a very severe case of Typhoid, under our care in King's College Hospital, with most alarming and profuse hemorrhage, we carried out a rigorous method of feeding with remarkably satisfacory results. The clear indication was to keep the intestines absolutely at rest and to allow no debris of food to pass through to excite peristaltic action. It was necessary therefore to give food which, while adequate to sustain and strengthen the patient, should be wholly absorbed in the stomach and upper part of the small intestines. To give milk might be fatal. For our purpose we selected VALENTINE'S MEAT-JUICE, giving one teasponful in a wineglassful of cold water every three hours, with one teaspoonful of brandy. The patient's diet was absolutely limited to these quantities for seven days. The plan answered admirably and the patient made a perfect recovery and fairly rapid convalescence."

Miscellany.

Adrenal Gland Secretion Found to Be Cause of Body Heat.—The mechanism by which the body keeps warm has received a new scientific explanation. Dr. Charles E. de M. Sajous, professor of endocrinology at the University of Pennsylvania, thinks that adrenin, the substance secreted by the adrenal glands, small organs just above the kidneys, plays an important part in the production of body heat. Physicians and biologists have known vaguely for years that heat is released by some process of union of the body cells with the oxygen of the air through the action of the blood in the tissues, but just what chemical changes are involved is still a mystery.

Dr. Sajous believes that adrenin is carried to the lungs where it takes up oxygen and is then absorbed by the red corpuscles of the blood and transported to the tissue cells. Here the complex chemical compounds that originate in the glands react with the partially digested food products to produce heat. This enables the enzymes or ferments present which are very sensitive to heat to complete the digestion of the food products, rendering them available for the work each tissue carries on.

This heat action must be so controlled, says Dr. Sajous, as to avoid excess heat, since any rise above 98.5° F., the normal temperature of the body, means fever. Any excess is normally prevented by the glandular substance cholesterol, while adequate production is assured by thyroxin, from the thyroid gland of the neck, which also acts as a stimulus to the gland product lecithin, the heat producer.

The beneficial effects of light and heat treatments, such as ultraviolet and x rays, are due to their speeding up this physiological process, says Dr. Sajous. This heat energy, by increasing the activity of the enzymes present in the tissue cells, enables them to break down the disease causing germs and the toxins they produce. Treatments with light and heat radiation are beneficial up to a certain limit but care must be exercised that they do not increase the body temperature beyond this point, Dr. Sajous declares.—*Science News Letter,* August 14, 1926.

Institute for Child Guidance.—The Commonwealth Fund of New York City is planning to establish in July, 1927, an Institute for Child Guidance as an outcome of its five years' investigations in the field of prevention of juvenile delinquency. The purposes of the institute will be to do research work in mental hygiene for children; to train psychiatrists and graduate psychologists in child welfare work, for which the National Committee for Mental Hygiene will give annual fellowships; to provide field training in practical child guidance for students in psychiatric work at the New York School for Social Work and the Smith College School for Social Work; to afford adequate clinical facilities for the thorough study of behavior problem children. Dr. Lawson A. Lowrey will be director of the new institute; the administrative board will include Dr. Frankwood L. Williams, medical director of the National Committee for Mental Hygiene; Porter R. Lee, New York School of Social Work; Everett Kimball, director of the Smith College School for Social Work; Dr. William A. White, director of St. Elizabeth's Hospital, Wash-

In Rheumatism, look for Intestinal Toxemia

Anti - Auto - Tox
Is indicated in
RHEUMATISM
as the blood stream poisons are eliminated, alkalinity of the blood increased and intestinal bacteria swept out of the system.

ANTI-AUTO-TOX
AGAINST SELF POISON

Anti - Auto - Tox
Gives prompt relief in
RHEUMATISM
The patient finds that muscular soreness, swollen joints, pain, etc., are readily relieved soon after treatment starts.

Medical authorities have claimed that Gout and Rheumatism are mainly caused by virile intestinal poisons absorbed by the blood and carried to all parts of the body, frequently lodging in joints and muscles causing intense pains.

Anti-Auto-Tox, within two days, restores the blood to its normal degree of alkalinity, brings about elimination of accumulated nitrogenized materials, augments the functional activity of the excretory system and completely overcomes intestinal stasis.

Anti-Auto-Tox presents the sulphates of potassium, magnesium and sodium in combination with the chloride of calcium and chloride of sodium in proportions in which these salts exert their most powerful influence on the organism.

Clinical Data—At our American and European headquarters, we have on file, hundreds of clinical endorsements of noted physicians as to the efficacy of Anti-Auto-Tox, and other diseases traceable to Autointoxication. We will gladly show these to any interested doctor.

Our Offer—A Sample of Anti-Auto-Tox will be sent to any doctor who requests our literature and will give Anti-Auto-Tox an honest test. We suggest you write us today.

For 20 years eminent physicians have effectively used Anti-Auto-Tox

Malaria Mosquitoes Controlled by Airplane Dusting.—Considerable success has attended the experiments of the United States Department of Agriculture in the use of the airplane as a means of distributing poison dust over both treeless and wooded swampy areas for control of malaria mosquitoes. In the final tests more than ninety-nine per cent. of the larvæ in the area treated were destroyed with one application. Paris green was the larvicide used in all the experiments. The procedure used in carrying out the tests is described in Department Circular 367, issued recently by the department.

In developing the method of handling the planes so as to distribute the dust properly and in determining the quantity of Paris green to use, flights were made first over open fields, then over dry woods, and finally over various types of mosquito breeding swamp and lake areas.

With an experienced pilot, and when careful attention was given to the spread of the dust, no special difficulty was encountered in distributing it over the treeless parts of the lakes. Furthermore, from a single experience in treating rice fields, this type of breeding place appears to be particularly well adapted to control by airplane dusting, because of the absence of trees and other obstructions which interfere with close flying. Even in such places as the heavily wooded areas where the water was protected by dense overhead foliage and where the planes had to be flown high enough from the ground to clear the tallest trees, the dust was found to have penetrated the thick growth and to have reached the water in sufficient quantities to destroy the larvæ.

The quantity of Paris green used in the experiments varied from about one twentieth of a pound to several pounds to the acre. Because of the small amount of poison required to kill the larvæ, the Paris green was mixed with an inert dust of some sort, finely ground silica earth being the carrier used in most cases.

In each test a series of pans containing known numbers of larvæ were distributed over the area to be dusted.

Two final tests gave particularly clear cut results, and for this reason were of special interest in showing the possibilities of this method of control in breeding areas of the type represented, the lakes overgrown with aquatic vegetation and having an abundance of Anopheles larvæ well distributed throughout. In the first of these a larval reduction of eighty-eight per cent. occurred as a result of the treatment, and in the second more than ninety-nine per cent. were killed. The only larvæ remaining in the second instance were a few of the smallest size, found in one small spot.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Registration of Births.—The recent health talks on the importance of birth registration broadcast from Station WGY were especially for the purpose of stimulating parents to make sure that their children's births are registered, without waiting for the time to come when legal evidence as to the time and place of birth will be needed and perhaps not be available.

One mother recently wrote to the Department enclosing the names and dates of birth of her five children and asked that this information be checked up against the records in order to make sure that all were registered. She had not "realized before how important it was to have a baby registered."

Parents should first consult the records of the registrar in the district in which their child was born. If the child's name can not be found the Department should be notified.—*Health News,* August 9, 1926.

Summer Hotel Guests Made Ill by Milk.—Nearly two thirds of the guests of a New York State hotel were made ill on July 10th and 14th, apparently through the consumption of milk from a cow having a diseased udder. Soon after the evening meal on Saturday, July 10th, fifteen or sixteen guests complained of pain in the abdomen, nausea, vomiting and diarrhea. The attacks, which lasted only a few hours, were followed by prostration from which the patients recovered on the following day. No further cases developed until Wednesday, July 14th, when about the same number were seized with similar symptoms from which they made an equally quick recovery.

An investigation of the outbreak by the local health officer and by the district state health officer showed that the only raw food consumed by all guests on the days mentioned was milk. As this was served every day an explanation of the cause of the outbreak was not forthcoming until it was found that the owner of the dairy supplying the hotel had noticed on Friday night, July 9th, that the udder of one cow was enormously swollen and that the milk from one quarter was tinged with blood. The remainder of the milk from this cow was at once discarded. The Friday night's supply was not used until Saturday, the day when the first cases appeared. According to the dairyman's story the milk from the sick cow was not used again. However, as he further stated that the milk appeared normal on Wednesday, July 14th, the supposition is that some, at least, found its way into the supply, since the second group of people became ill on that day.

That this milk was the cause of the outbreak is further confirmed by two cases which present practically indisputable evidence. A son of the proprietor became ill about an hour before anyone else on Saturday. At first he denied having had any milk but a waitress reminded him that he had had a glass of milk and some cake about an hour before the evening meal. A physician who was called to see some of the first cases about two A. M. Sunday, drank a glass of milk while at the hotel, having taken no food since Saturday noon. He was awakened before daybreak Sunday by symptoms similar to those he had been treating.

Samples of the suspected milk were sent to the State Laboratory for examination. No report was available at the time this item was written.

The symptoms and temporary nature of the outbreak were very similar to those reported from Seneca Falls.—*Health News* August 9, 1926.

(Formula Dr. John P. Gray)

has proven an ideal supportive and reconstructive.

Especially is Gray's Glycerine Tonic Comp. a satisfactory ***succedaneum*** for cod liver oil, or other products apt to place an extra tax on the digestion, for it aids rather than burdens the digestive organs, and increases rather than lowers the appetite and intake of food.

One of the main reasons, therefore, why so many physicians have come to use and highly appreciate Gray's Glycerine Tonic Comp. is that they have found it can be administered as freely in the Summer as at any other time of the year in the treatment of their convalescent, debilitated and elderly patients.

Valentine's Meat-Juice

In **Hospital** and **Private Practice** and **in their own persons** when ill, **Physicians** have demonstrated the **Power** of **Valentine's Meat-Juice** to **Sustain** and **Strengthen** the **Weakened Vital Forces** when the **Digestive Organs** are **Impaired.**

Debility, Exhaustion and Anaemia

Dr. Julian Calleja, *Pres. Royal Academy of Medicine of Madrid, Spain:* "It is with the greatest satisfaction I inform you that I consider VALENTINE'S PREPARATION OF MEAT-JUICE to be of a very superior order for invigorating the nervous system, for which I use it myself and prescribe it to my patients."

John Tanner, M. D., LL. D., *Senior Physician Farringdon General Dispensary for Diseases of Women and Children, London, England:* "In cases of Flooding or Hemorrhage of any kind, Fevers, low forms of Pneumonia, Extreme Exhaustion when the stomach is too irritable to retain any ordinary preparation, then VALENTINE'S MEAT-JUICE will be found to be a perfect God-send. I cannot speak too highly of it, as I have found it of such immense advantage to me in the treatment of the most anxious and serious cases under my care."

VALENTINE'S PREPARATION
NUTRIO
PER ME
VOLUME 1 4/5 OZ.
MEAT JUICE
The result of an Original Process of preparing Meat and extracting its Juice by which the elements of nutrition are obtained in a State ready for immediate absorption.
DIRECTIONS. Dissolve one teaspoonful of the Preparation in three tablespoonfuls of cold or warm water, boiling water changes the character of the preparation

Physicians are invited to send for brochures containing clinical reports.

Miscellany.

Medical and Scientific Chronology in Philadelphia for 150 Years.—An interesting and useful little leaflet has been issued by Blakiston's Son & Company, publishers of Philadelphia, evidently for distribution to visitors at the Sesquicentennial Exposition. It contains a table of 150 years of medical and scientific chronology in Philadelphia which is interesting enough to warrant quoting: 1682, John Key, first white child born in Philadelphia; laid corner stone of Pennsylvania Hospital, 1755; 1683, first school; William Penn Charter opened; 1727, American Philosophical Society founded by Franklin; 1731, first library established by Franklin; 1732, David Rittenhouse inventor of Improved Orrery; Philadelphia Hospital and Insane Asylum established; 1736, Franklin's son died; smallpox; Franklin said: "I regret he was not inoculated"; 1740, University of Pennsylvania founded; 1745, first American Medical Journal; Cadwallader's Treatise on the West India Grippe; 1747-53, Franklin's electrical experiments; 1751, Pennsylvania Hospital for Poor Sick Persons; 1755, first commencement at University of Pennsylvania; Francis Hopkinson one of the graduates; 1756, first comprehensive college curriculum formulated by provost of the University of Pennsylvania; 1762, Dr. William Shippen lectures on anatomy; 1765, Medical School of University of Pennsylvania founded; Dr. John Morgan lectures on medicine; Philadelphia County Medical Society organized; 1768, first American diploma awarded in medicine; 1769, Dr. Benjamin Rush, professor of chemistry at the University of Pennsylvania; 1773, American Medical Society founded; existed until 1793; Dr. William Shippen, Jr., president in 1790; 1779, first State University created; included College of Philadelphia, founded 1740, which became University of Pennsylvania, 1791; 1786, Philadelphia Dispensary founded; 1787, College of Physicians of Philadelphia founded; 1788, action initiated towards preparation of a pharmacopœia; 1793, J. G. Mancrede first to propose Cæsarean section; special meeting of physicians to study yellow fever; Dewees, noted obstetrician, began practice in Philadelphia; 1794, committee of physicians consider health laws; 1804, Medical Lyceum; 1805, Dr. Philip Syng Physick in chair of surgery at the University of Pennsylvania; a pupil of John Hunter; 1812, Academy of Natural Sciences; 1818, T. Hensen prepared first and second United States Pharmacopœia; 1821, Philadelphia College of Pharmacy; 1824, Franklin Institute; 1825, Jefferson Medical College; 1827, Horticultural Society, first of its kind in America; 1831, Dr. Philip Syng Physick operated for gravel on Chief Justice Marshall and removed over one thousand calculi; 1833, Girard College; 1834, Wills Eye Hospital; 1843, Blakiston Publishing House established; 1848, Hahnemann Medical College organized; 1850, Eclectic Medical College of Pennsylvania chartered; first woman's medical college in the world; Philadelphia Lying-In Asylum organized; 1862, Spring Garden Institute; 1863, beginning of medical specialization; laryngology one of the first; 1864, clinics at Pennsylvania General Hospital opened to mixed classes; 1874, first teaching hospital—University Medical School; 1877, Jefferson Hospital (original) built; 1881, Wharton School; 1882, Directory of Nurses; 1883, Veterinary School and Hospital, University of Pennsylvania; 1884, first electrical exhibition in America; 1886, state weather service planned; 1891, Committee to advocate State Board of Medical Examiners and Licensers; 1893, first case of hookworm disease reported in Philadelphia; 1915, Dental School, Evans Institute, University of Pennsylvania; 1916, Graduate School of Medicine, University of Pennsylvania; 1921, Bartol Research Foundation, Franklin Institute.

Jamestown Eye Survey.—An eye survey of 8,000 children in the city of Jamestown, New York, has recently been completed by the State Medical Inspection Bureau working in cooperation with the National Committee for the Prevention of Blindness, the New York State Commission for the Blind and the Jamestown Board of Education. This survey was undertaken because authentic data on defective vision of children available to a fair degree for large cities and rural sections, was notably lacking for medium size cities. Jamestown was chosen because it belonged in this class, possessed school buildings ranging from old fashioned to strictly modern, had a health inspection system into which eye testing could be satisfactorily introduced and a board of education which promised cooperation.

Some of the more important findings were:

The percentage of defects found in this survey, when classified by the grouping in common use throughout the country, was eighteen per cent. (figures based on the usual classification) as compared with the twelve per cent. estimate of the Joint Committee on Health Problems of the National Education Association and the American Medical Association. This is not an indication of an increase in defects but of the observance of a little more accuracy in testing the acuity of vision.

2. A definite program on eye hygiene, which consists not only of correcting defective vision but conserving all vision.

3. A more inclusive grouping which will route all potential defective vision cases for a complete examination. . . .

4. Appreciation of the necessity for an ophthalmological study of the farsighted as well as the nearsighted child. . . .

5. Further observation of the relationship between defective vision and retardation. . . .

The amount of defective vision . . . was eighteen per cent. . . .

The percentage of defective vision which may readily be corrected in a few months' time through the social facilities available . . . was approximately thirty per cent. . . .

About one in every 286 of the school children has sufficiently defective vision to warrant specialized education for him. Thirty-one such children were found. . . .

It costs the board of education of a city having a school population of 8,000 children an estimated minimum of $300 every year for retardation of school children whose eye defects are the contributing factor in their retardation. This figure was furnished by the board of education of Jamestown.

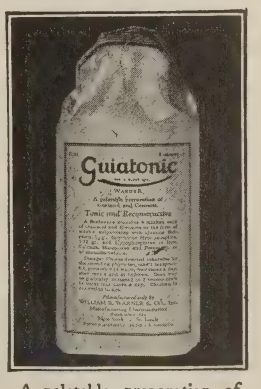
"When the Bodily Fires Burn Low"

and the various organs are not functioning as they should, it is essential not only to increase the appetite, but also to raise the capacity of the body to take care of the increased intake of food that naturally follows.

The efficiency of GUIATONIC in accomplishing the foregoing, has led to its adoption by many physicians as their favorite recuperative agent and all-round tonic. They have learned that when they prescribe Guiatonic *the results are seldom in doubt.*



A palatable preparation of special salts of guaiacol and creosote which may be freely given to the weakest patient, without fear of gastric disturbance. *It contains no narcotics.*

Indicated in all depressed or debilitated conditions, or whenever a tonic is required.

Guiatonic

A liberal supply for testing free to physicians. William R. Warner & Company, Inc., Manufacturing Pharmaceutists since 1856. 113-123 West 18th Street, New York City

United States Smallpox Rate in 1925.—The United States has the unenviable distinction of reporting more smallpox during 1925 than any other country except India, namely 43,193 cases, according to reports which have been received by the American Association for Medical Progress from the health officers of all but one state (Utah). This shows a substantial improvement over 1924, when we boasted 56,351 cases. Moreover, the last six months of the year 1925 gave less than half as many cases as were reported for the first six months. On the other hand, there has been a large increase in the proportion of deaths from smallpox since January 1st in California and other places.

Most of the states do not report the vaccinal condition in cases of smallpox. In seventeen states and the District of Columbia such reports are available for most of the cases—10,636 out of the total of 12,858 cases in these states. Among these, over nine tenths, or 9,660 cases, had never been vaccinated, and 751 cases, about seven per cent., had been vaccinated from seven to fifty years previously.

Thirteen states each reported more than one thousand cases of smallpox in 1925, California leading with 4,921 cases, followed closely by Alabama (4,288), and Ohio (4,018). Indiana had 2,996 cases; Georgia, 2,108; Washington, 2,004; North Carolina, 1,920; Tennessee, 1,805; Kentucky, 1,700; Illinois, 1,625; Wisconsin, 1,517; Texas, 1,309; Mississippi, 1,216.

All of the six New England States together had only 102 cases, ninety-four of which were in Rhode Island.—*Medical Week,* August 14, 1926.

Travelers and Health.—Americans are rapidly becoming a nation of travelers. By land and water they are increasingly on the move. From many sections of the country reports indicate that the traveling public is presenting social, economic, and health problems of no mean proportions. To meet the situation provision is being made in a few large cities for a twenty-four hour information and medical service, but in smaller communities the harassed traveler is at the mercy of hotel attaches or other strangers. Medical attention is often required in an emergency, and when neglected, fatal results may follow.

The arrangements being perfected by traveling men's associations whereby reliable medical service may be obtained in towns of over ten thousand population is a movement of first importance. As the tide of travel increases the number of physicians doing such work will surely increase. The results of their treatment will be checked by physicians in other cities, and thus one more activity of the medical profession will assume a public health aspect. The physician's influence will be limited only by the movements of his traveling patients and his ability or lack of ability will be paraded in many far away places. This should stimulate a desire to render the best possible service, and whet the ambitions of the progressive physician to keep abreast of advances in medical practices, knowing that his work will be reviewed by other practitioners.

Thus, the wanderlust which has laid hold of such a large proportion of the population is broadening the influence of medical treatment in its public health relations.—*The Nation's Health,* April, 1926.

Origin of Porcelain Teeth.—The use of porcelain for dental purposes, according to *La Thérapeutique,* had its origin in France at the beginning of the eighteenth century. Credit for the invention belongs partly to a pharmacist, Duchâteau, of Saint Germain en Laye. His idea would have had no practical results without the cooperation of the dentist, Dubois de Chemant, who brought about its materialization.

Duchâteau was the possessor of a set of false teeth made of ivory which had acquired a most offensive odor. He had the idea of making on the same model a porcelain set. After several unsuccessful attempts he succeeded, with the help of Dubois de Chemant, in making a usable appliance. While Duchâteau was trying to commercialize sets of mineral materials, de Chemant, little by little, was perfecting mineral compositions. In 1788 he published his first monograph on mineral teeth.—*Translated from Aesculape.*

Cyrus the Great Used Boiled Water.—Herodotus, Book I, Chapter 189, states that the Cyrus the Great of Persia, on his military expeditions, carried with him boiled water from the Coaspes River in silver vessels on four wheeled wagons. As this ruler died about 530 B.C., it is apparent that for nearly twenty-five centuries military leaders failed to take advantage of this lesson which these ancient rulers had learned, or to grasp its significance. Aristotle is credited with having advised Alexander the Great to boil all the water carried on his marches through the desert to keep it from getting "sour."—*Health News.*

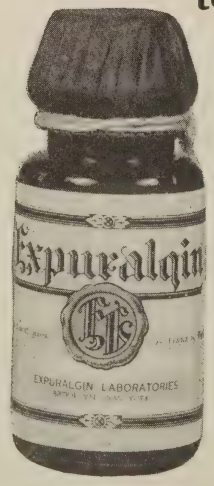
Pullman Porters All Vaccinated.—The report of the discovery of a number of cases of smallpox among negroes employed in brickyards along the Hudson River was brought by the Department to the attention of Dr. Thomas R. Crowder, Director of the Department of Sanitation and Surgery of the Pullman Company. In a letter Dr. Crowder states that before a negro is taken into the service of the company as a porter he must either be vaccinated or show evidence of a recent successful vaccination. The physician making the examination must satisfy himself that the scar is less than five years old; if older than this, at least one attempt at reinoculation is required. Applicants must also be examined as to physical fitness. Approximately 12,000 negroes are employed by the company as car porters.—*Health News,* August 9, 1926.

Westchester County Sanitary Commission.—Three quarters of the population of Westchester County, which approximates half a million people, will have the benefit of a comprehensive sewer system and sewage disposal works if plans outlined by the Westchester County Sanitary Commission at a recent meeting are carried out. A report of the survey of the Saw Mill River valley sewage project was made to the Commission by W. W. Young, the chief engineer, and a former member of the staff of the Division of Sanitation. He was instructed by the Commission to proceed with all possible speed to complete the survey of the Mamaroneck and Hutchinson River valley projects. The proposition will then have to go before the people for adoption.—*Health News,* August 9, 1926.

It will be a revelation to you to use

EXPURALGIN (Magnesium-Potassium Acetyl Citrate)

to replace Salicylate therapy



DOSAGE—10 to 15 grains every three hours until acute pain abates; then 10 grains every four to five hours. In Hypertension 10 grains three times a day; reduce dosage as blood pressure shows desired decrease.

ADVANTAGES—

1) Not toxic in large therapeutic doses.
2) Causes no gastric disturbances, or other ill-effects known to be produced by Salicylates and allied coal-tar products.
3) A strikingly more powerful analgesic and anti-rheumatic, than Salicylates.
4) Possesses the property of producing LEUCOCYTOSIS to a marked degree; an essential factor in inflammatory conditions.
5) A mild, but positive diuretic.
6) An effective vaso-dilator, hence very desirable in cases of HYPERTENSION.

INDICATIONS—

Rheumatic diathesis, Neuralgia, Neuritis, Myositis, Catarrhal inflammation of the respiratory tract, Influenza, Pleurisy. Essential or toxic HYPERTENSION.

Descriptive literature and samples on request.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Children's Bureau Exhibit at Sesquicentennial.—A baby's "fashion show," a model nursery, a model playground, moving pictures and film slides, and a children's clinic in active operation are among the exhibits of the Children's Bureau at the Sesquicentennial in Philadelphia, according to the *Medical Woman's Journal.* There is also a "mechanical book" on the constantly turning pages of which may be read in large figures the infant and maternal mortality record of the United States, the former fairly good, and the latter very far from creditable. Dominating the whole and striking the keystone of the exhibit and of the work of the Children's Bureau, is the great mural painting entitled "The Child Shall Be First," painted for the Bureau by Peppino Mangravite. This faces the entrance to the Children's Bureau Exhibit. Two motion pictures are shown, one, *Well Born,* demonstrating simply and convincingly the essentials of prenatal care; the other, *Posture,* a film produced under the direction of Dr. Armin Klein, whose work as director of the posture clinic of the Massachusetts General Hospital and of posture clinics for the city health department of Boston has attracted wide attention.

Sleeping Sickness Victims Reeducated Like Cripples.—Children whose characters are strangely warped as a result of the European sleeping sickness have crippled brains and may be classed with crippled children, even though they have no visible deformity of body. This new idea in dealing with the serious aftereffects of sleeping sickness is proposed by Miss Holvi Haahti, a Finnish psychiatrist who has been conducting tests at the Institute of Juvenile Research of Illinois.

The number of children who are left by this disease with overpowering desires to steal, commit sex offenses, lie, and run away from home is sufficient to make them a serious social problem, but most cities have made no special provision for their education or retraining. Miss Haahti reports that as an experiment seven children who had had sleeping sickness were admitted to a special school for physically crippled children, in Chicago, and were treated like the other cripples, with promising results.

Sleeping sickness victims, who were often quiet, well behaved children before the attack, are usually considered bad because of their strange behavior, and are dealt with accordingly by parents and teachers, she states. In the special school for cripples these children were in close contact with teachers who understood the defects and with children who know that they were "sick" just like the rest of the class except that the disability was in a different part of the body.

The chief problem is to reestablish the child's good physical and mental habits, which were destroyed during the acute stage of the disease, Miss Haahti states. Typical physical bad habits of these children are a peculiar gait, and jerky, awkward movements of the arms, which indicate the same lack of self control that leads them to fall into violent rages or to steal money from a neighbor.

She finds that "the question which has not yet been sufficiently answered is whether these good habits can be reestablished by careful habit training over a long period of time, or whether the nerve paths were permanently destroyed by the disease so that retraining would not be possible."—*Science News-Letter,* August 21, 1926.

Tuberculosis in New York City.—During the first four months of 1926 twenty tuberculosis hospitals serving New York City cared for 7,250 patients, according to a report made by Godias J. Drolet, consulting statistician of the Tuberculosis Sanatorium Conference of metropolitan New York at its bimonthly meeting held June 9th at Seton Hospital, Spuyten Duyvil.

On May 1st, Mr. Drolet reported, all known cases of tuberculosis in New York City recorded at the Department of Health totaled 26,254. During January and February of this year deaths from the disease were fewer than a year ago, but in April and May the number of deaths slightly exceeded the record for those months in 1925.

More than nine thousand tuberculous patients were entertained during the last four months in 328 wards of fourteen hospitals and sanatoria by concerts arranged by the New York Tuberculosis and Health Association, according to a report made by Frederic D. Bell, secretary of the Conference and director of the Hospital Service Department of the Association. Two hundred and ninety-nine musicians and entertainers volunteered their services for these concerts.

Rev. Joseph S. O'Connell reported that the Catholic Church maintains twenty-six day nurseries in New York where regular medical supervision of the 2,500 children who attend them is used to discover incipient cases of tuberculosis.—*N. Y. Medical Week.*

Cremation.—As the population for a country grows larger and an increasing proportion of it migrates to the cities, disposal of the dead becomes a problem. Even now, in some communities, the economic loss from maintaining inviolable cemeteries is tremendous. The esthetic aspect, furthermore, has considerable weight, as burying grounds may be unsightly; and they injure real estate values. The practical alternative to earth burial is cremation. In the United States, although thinking people have long favored the method, cremation has not been widely adopted. Greater progress has been made in other places. Zurich, in Switzerland, for instance, allows interment in a suitable place but does not provide facilities for it. On the other hand, every facility for cremation is provided. A Japanese has recently developed a smokeless and odorless crematory in which combustion is rapid and which requires little fuel. In England, also, cremation is gaining favor. The number of cremations in Great Britain has increased from 445 in 1901 to 2,701 in 1925. This progress, however, was not effected until the Cremation Society of England spent much effort on education of people in the idea. During this process of education, it was discovered that the public shunned the subject of what happens to the body after death. They were willing, however, to discuss the esthetic and sentimental aspects of the question. Beautiful gardens in which ashes might be dispersed appealed to them as a fitting, living memorial to the dead, much more appropriate than the traditional cemetery.—*Journal A. M. A.,* August 14, 1926.

IN GETTING CHILDREN READY FOR SCHOOL

an important item to remember is to put those who are anemic, or run-down, on an agent calculated to build them up and enable them to meet the heavy demands of the school term.

by reason of its blood and tissue making properties meets the indications in these cases and without causing gastric disturbances.

You will find Cord. Ext. Ol. Morrhuae Comp. (Hagee) a reliable reconstructive and so acceptable that it may be continued indefinitely.

Have you a "catheter case" in which you would like to use "K-Y" Lubricating Jelly?

We are so confident that K-Y Lubricating Jelly can and will bring a new era of safety and comfort to the unfortunate person whose very existence is dependent upon the constant use of the catheter, that we are anxious to send you, upon request, a large size tube of K-Y Lubricating Jelly for the catheter case in which you might wish to use it. This would give your patient an opportunity to make the trial without expense.

When you feel utterly tired and worn out, you will be agreeably surprised what prompt relief and what a noticeable sense of refreshment you can obtain by applying K-Y ANALGESIC (non-greasy and water-soluble) to the forehead. Without harmful after-effect, it will often help you to "live out" the tedious day, and face its many exacting duties.

Alma Mater Home Coming.—Dr. Charles Geiger, president of the Alumni Association of the Ensworth-Central Medical College has extended to the Alumni Association a cordial invitation to hold the second annual meeting and banquet in St. Joseph, Mo., at the St. Francis Hotel, as his guests. The invitation is a "blanket" one and includes all graduates of the Ensworth-Central and Northwestern Colleges, as well as the professors. An entertaining program is being arranged, including Dr. Geiger's moving picture lecture, illustrating his recent world cruise and report on clinics in the far East. The meeting will be held on Wednesday evening, October 13th, during the Kansas City Fall Clinical Week. Wednesday evening is to be entirely devoted to alumni dinners at the Kansas City Clinics, so the members will miss no part of the program by attending the banquet in St. Joseph. Dr. Charles Wood Fassett, Secretary, of 115 East Thirty-first Street, Kansas City, Mo., is secretary of the association.

European Tour of American Physicians Winds up with Banquet in New York.—The well known New York surgeon, Dr. F. H. Albee, who returned to New York a few days ahead of his travel companions from the trip of the Travel Study Club of American Physicians to Europe, had invited all the participants of the tour to a welcome and at the same time a farewell dinner at the Fraternity Club, 22 East Twenty-eighth Street, New York City, on Monday night, August 9th, that is, on the day of the return of the party, before they would depart for California, Florida, and wherever their homes may be. Dr. Albee extended a hearty welcome to his travel companions. All through the evening it was heard what an interesting and wonderful time everybody had. Much praise was given to the German resorts and German medical science. Memories of the trip were exchanged and after the showing of lantern slides of pictures taken on the tour through Switzerland and German resorts the guests parted. Among those present were Dr. L. L. Seaman, 20 Fifth Avenue, N. Y., the president of the club, and Dr. Richard Kovacs of 223 East Sixty-eighth Street, the secretary of the club and conductor of the tour, and all the other participants of the tour. One of the guests invited was Dr. A. H. Applemann, the representative of the German Health Resorts, 630 Fifth Avenue, who had prepared the trip through the German resorts.

Foot and Mouth Disease Specialists Return.—The foot and mouth disease commission sent to Europe to study the research being done there on the problem has returned after more than a year's stay. The commission, which consists of Dr. Peter K. Olitsky of the Rockefeller Institute for Medical Research, Dr. Jacob Traum of the University of California, and Dr. Henry W. Schoening of the Federal Bureau of Animal Industry, is now engaged in writing its report of the survey. After studying research work and control measures employed in France, Germany, England, Denmark, Sweden, Holland, Belgium, Switzerland, Austria, Hungary, and Italy, the commission established itself at the *Institut d'Hygiène*, Strasbourg, and later at the *Laboratoire National de Récherches*, Alfort, France. Experimental studies were made at these institutions on the causual agent of foot and mouth disease from its physical, chemical and biological aspects. Particular attention was given to certain phases of the problem bearing on methods of control of the disease used in this country.

Research on Sleep.—In 1924 the Simmons Fellowship was founded at Mellon Institute of Industrial Research, University of Pittsburgh, to carry on a broad study of problems in the promotion and maintenance of healthful sleep. Dr. H. M. Johnson and Mr. G. E. Weigand, psychologists, and Dr. T. H. Swan, physical chemist, have been conducting this research during the past year. Recently Dr. Carney Landis, physiologist, has temporarily joined the personnel of the investigation. It has recently been announced that from now on there will be two separate Simmons Fellowships at Mellon Institute. One of them will continue the research on the physiological and psychological factors of sleep under the supervision of Dr. Johnson. The other, held by Dr. Swan, will be concerned chiefly with the subject of bedding materials. This investigational work is being supported primarily for the benefit of the public, consequently the experimental results will be published.

For the Young

A tonic of exceptional efficiency in convalescence and "run-down" conditions of childhood. Palatable, and readily taken by the youngest children, without the slightest unpleasant action, it is a dependable body-builder at all seasons of the year.

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

A restorative and reconstructive, invaluable for aiding and promoting the activity of the weakened functions of the aged. Especially serviceable after debilitating or exhausting diseases, and for counteracting the depressing effects of overwork and worry.

A remarkably useful agent in the digestive and nutritional disorders of the elderly.

For the Elderly

Miscellany.

Tobacco Smoking and Scholarship.—J. Rosslyn Earp, of Antioch College, has just investigated the long run effect of tobacco on college men. As a result of his research, he announces that those students who inhale the fumes of tobacco, regardless of whether they smoke much or little, have lower scholarship records than smoking students who do not inhale. This fits in with the statement of a German scientist, who recently reported that inhalers take into their systems eight times as much nicotine as smokers who do not inhale, Mr. Earp says.

The effect of smoking is chiefly shown in mental fitness, the experiments at Antioch College indicate. When smokers and nonsmokers were given physical tests Mr. Earp could discover no significant difference between the pulse rates, blood pressure, or heart efficiency of the two classes. But when he looked up scholarship records, covering a long period of time, he found a striking difference in his figures. "Although the number of smokers and nonsmokers in the college is practically the same, yet out of twenty-three students dismissed last year for low scholarship no less than twenty-one were smokers," he says. "As one ascends the scale of scholarship, the proportion of nonsmokers grew steadily greater. And, in general, those who smoke much have lower scholarships than those who smoke little."

The significance of these findings is increased by the fact that they have been carefully subjected to mathematical processes to measure the reliability of the results. Mr. Earp believes that this is the first time that the effect of inhaling on scholarship has been measured, and he thinks that the figures may be "of some importance, since they indicate that the lowered mental efficiency is not just a coincidence but actually a consequence of smoking."—*Science News-Letter,* August 14, 1926.

Residual Effects of War Gas.—The Board of Medical Officers, appointed by the director of the United States Veterans' Bureau to study the residual effects of war gas, expects to complete its studies of chlorine gassing by the first of the year. The Board, which held its first meeting March 9, 1926, is composed of Dr. Allen K. Krause, associate professor of medicine at Johns Hopkins University; Lieutenant Colonel Harry L. Gilchrist, M.C., U.S.A., chief of the Research Division, Chemical Warfare Service, and Dr. Philip B. Matz, chief of the Medical Research Subdivision, United States Veterans' Bureau.

Records show that approximately seventy thousand men were gas casualties of varying degrees of severity during the war, 1,843 of which were from chlorine gas. The War Department has made an investigation of the immediate effects of chlorine gassing in over eight hundred cases, and the present study by the Veterans' Bureau is expected to develop important information pertaining to the residual effects of this gas.

Upon completion of their investigation of chlorine gassing, the board will commence a survey of the cases resulting from phosgene, mustard, and other gases.

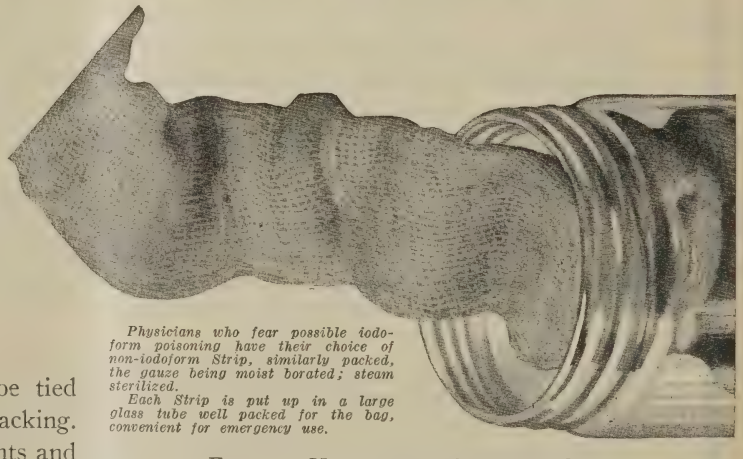
When Post-Partum Hemorrhage Occurs—

one of the best measures at the command of the attending physician is immediate and liberal stuffing of the bleeding uterus.

The Post-Partum Uterine Packing Strip has been designed in every way best to meet these requirements.

It consists of 10 yards of Iodoform Gauze (5%), of suitable bulkiness 8 inches wide folded to 1 inch easily introduced into the canal. In extreme cases, two Strips may be tied together to provide 20 yards of continuous packing. The glass tube assures protection to the contents and offers quick access to either screw-cap end.

While it is fortunate that this complication arises comparatively infrequently, it is nevertheless an ever-present possibility, and the physician who always carries in his obstetrical bag one or two Post-Partum Uterine Packing Strips sooner or later is very glad of his foresight.



Physicians who fear possible iodoform poisoning have their choice of non-iodoform Strip, similarly packed, the gauze being moist borated; steam sterilized.

Each Strip is put up in a large glass tube well packed for the bag, convenient for emergency use.

EQUALLY VALUABLE IN PLACENTA PRÆVIA

Public Health Instruction Extended at Columbia.—Columbia University's public health work, carried on through the DeLamar Institute of Public Health, will be extended this year, it was announced on August 22d by President Nicholas Murray Butler. Its object, said the announcement, is to "extend to the lay public through channels of popular education the benefits of reliable information in the protection and development of human health and in the prevention of disease."

This is in accordance with the provisions in the will of the late Joseph P. DeLamar, under which funds were provided for the institute. The institute is a part of the School of Medicine and is under the direction of Dr. Haven Emerson.

Beginning with the coming academic year the degrees of Master of Science and Doctor of Philosophy will be awarded by the institute. The master's degree will be available to students who have completed a year's study, including three months of practical field, laboratory or administrative work in the summer session. Granting of the degree is subject to the same requirements as are in force in other departments of the university.

"The staff of the Institute of Public Health," Dr. Emerson said, "is now authorized by the university to embark upon the training of sanitarians, health officers, directors of medical services of industrial plants, and vital statisticians, as well as of others who wish to qualify in a postgraduate school after they have graduated as physicians or obtained the degree of B.S. or B.A. and have acquired special additional training in the natural sciences, such as botany, chemistry and physics and also in mathematics.

"The institute will continue to aid in developing public health services, local and national, through a multitude of special health organizations.

"Field nurses of health departments, nutrition workers, bedside nurses of visiting nurse associations are some of the agents, and lectures on tuberculosis, child hygiene and other similar subjects are some of the means by which the institute is able to popularize health education."—*New York Medical Week,* September 4, 1926.

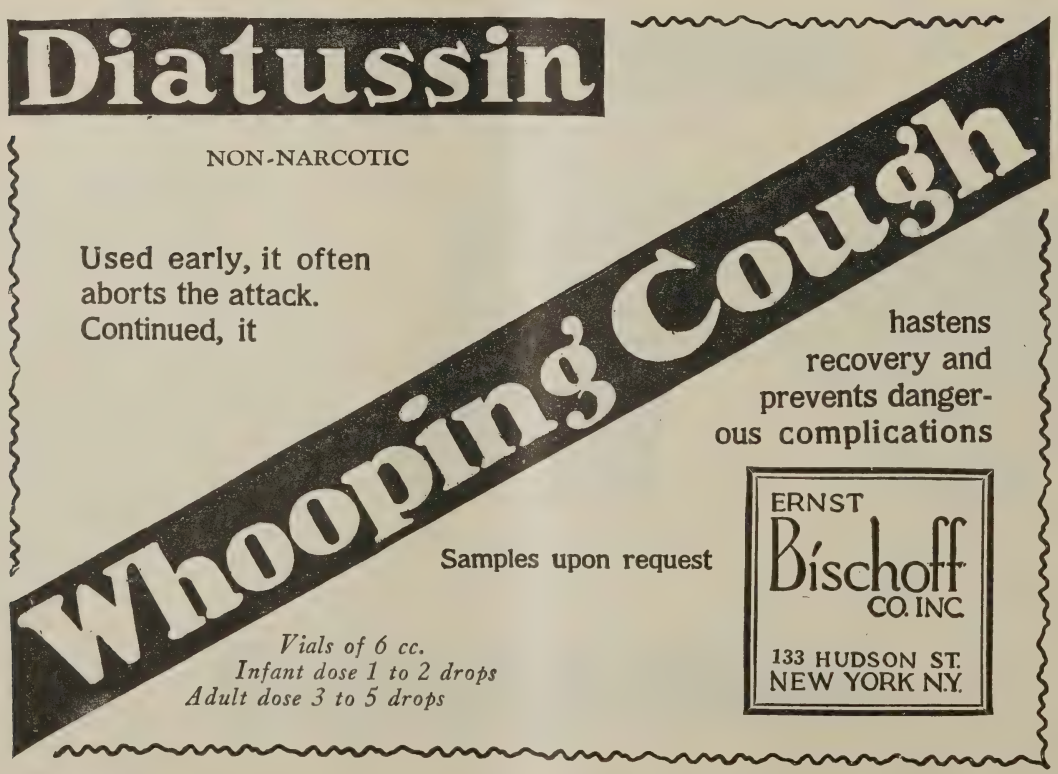
Fifth edition, completely revised and enlarged. Volume II. Illustrated. St. Louis: The C. V. Mosby Company, 1926. Pp. 702.



During the Summer Months the question of what measures to employ to restore —and maintain—the nutritional balance, is often a difficult one. The digestive and assimilative functions tend to become inactive, and the natural trend of the body is toward loss of vitality and weight.

At this season—and under these conditions

Gray's Glycerine Tonic Comp.

(Formula Dr. John P. Gray)

has proven an ideal supportive and reconstructive.

Especially is Gray's Glycerine Tonic Comp. a satisfactory ***succedaneum*** for cod liver oil, or other products apt to place an extra tax on the digestion, for it aids rather than burdens the digestive organs, and increases rather than lowers the appetite and intake of food.

One of the main reasons, therefore, why so many physicians have come to use and highly appreciate Gray's Glycerine Tonic Comp. is that they have found it can be administered as freely in the Summer as at any other time of the year in the treatment of their convalescent, debilitated and elderly patients.

Tuberculosis

Robert Alfred Bindley, M. D., *Late Resident Medical Officer North London Hospital for Consumption:* "I used considerable quantities of VALENTINE'S MEAT-JUICE when Resident Medical Officer of the North London Hospital for Consumption, and consider it of great use in feeding up those who are in a wasted condition, and who suffer severely from digestive disturbances."

Pietro Borromeo, *Physician and Surgeon of the Hospitals of Rome, Italy:* "I have tried VALENTINE'S MEAT-JUICE in the Tuberculosis Division of the Hospital of the Holy Spirit, and have proved the great advantages that it renders for the nutrition of the Consumptive. Pleasant to the most fastidious taste of the sick, it does not irritate the stomach; but stimulates the peptogastric functions so as to improve notably the appetite, even in cases of continuous and high fever and of extreme loss of strength."

Miscellany.

Rudyard Kipling on Public Health.—Into his tales Kipling has woven incidents that to the governmental authorities of England's tropical colonies were serious problems in the administration of public health service, writes Dr. Louis J. Bragman (*American Journal of Public Health,* June, 1926). Colonial rulers soon learned that their power in India lay not in the numbers but in the physical strength of their forces. Public health became an item in their administrative program. The struggles they encountered in inaugurating protective hygienic measures and their efforts in combating the tremendous mortality in many instances gave Kipling a background for his stories. In *A Trooper of Horses* he writes: "We have no smallpox or disease here," quoting the words of a native soldier of India. "The doctors are strict and refuse is burned by the sweepers. It is said that there is no physician like fire. He leaves nothing to the flies. It is said that flies produce sickness, especially when they are allowed to sit on the nostrils and the eyes of children or to fall in their milk pots." In the *Tomb of His Ancestors* Kipling vividly describes the efforts with final victory to overcome the superstitious fear of vaccination in an out of the way jungle village. The people said: "One came to us in the name of the Government with little ghost knives and a magic calf, meaning to turn us into cattle by the cutting off of our arms." To this the official, rolling up his sleeves and showing his vaccination scars, replied: "You know the Smallpox who pits and scars your children so that they look like wasp combs. It is an order of the Government that wohso is scratched on the arm with these little knives which I hold up is charmed against her. All Sahibs are thus charmed, and very many Hindoos. I myself will stay among you while this man scratches your arms with the knives. In three or it may be five or seven days, your arms will swell and itch and burn. That is the power of the Smallpox fighting in your base blood, against the orders of the Government." The people were finally reassured, and soon it was considered a mark of great honor to have a vaccination scar, and the practice became almost universal.

The Indian doctor in *The End of the Passage* tells of the gruesome ravages of cholera: "About fifteen deaths a day don't incite a man to shoot anything but himself. And the worst of it is that the poor devils look at you as though you ought to save them. Lord knows, I've tried everything. My last attempt was empirical, but it pulled an old man through. He was brought to me apparently past hope, and I gave him gin and Worcester sauce with cayenne. It cured him; but I don't recommend it." When this doctor was asked how the cases ran, he replied: "Very simple indeed. Chlorodyne, opium pill, chlorodyne, collapse, nitre, bricks to the feet, and then the burning ghat. The last seems to be the only thing that stops the trouble. It is the black cholera, you know." The same scourge and its ravages are described in the poems, *Death Bed, Cholera Camp,* the *Spies' March,* and *Natural Theology.* A picturesque interpretation of the plague and its epidemiological and preventive aspects is also given in the stories entitled *A Germ Destroyer,* and *A Doctor of Medicine.*

In *William the Conqueror,* one of Kipling's masterpieces, the Delhi sore, made epidemic by a protozoan parasite, and its disfiguring consequences, is mentioned. "Her face was as white as bone and in the center of the forehead was a big, silvery scar about the size of a shilling—the mark of a Delhi sore, which is the same as a 'Bagdad date.' This comes from drinking bad water and slowly eats into the flesh until it is ripe enough to be burned out."

Concerning typhoid fever it is stated in *By Word of Mouth,* "Nearly every household in India knows that doctors are very helpless in typhoid. The battle must be fought out between Death and the nurses minute by minute and degree by degree."

The Sixty-eighth Congress and Health.—"The Sixty-eighth Congress, which became a matter of history on March 4, 1925," writes James A. Tobey in the *American Journal of Public Health* for April, "will probably be remembered, if at all, for the legislation which it failed to pass, rather than for that which it did pass." Dr. Tobey goes on to review this legislation as a whole.

The measures relating to public health which became laws included prohibition of pollution of coastal waters by vessels; extension of the maternity and infancy acts to certain of the territories; a vocational rehabilitation act; provision for participation in an international narcotic conference; prohibition of the importation of crude opium; codification of laws pertaining to veterans; various appropriations for public health, usually less than in previous years; a special appropriation of $275,000 for plague prevention; a special appropriation of $57,600 for investigation of oyster pollution; more hospitals for veterans; establishment of a dairy bureau in the Department of Agriculture; and a number of other measures of less importance, though several bills relating to public health in the District of Columbia, such as control of milk, dentistry, optometry, and venereal diseases, are of great significance to people of that district.

Among new laws of general scope are acts relating to immigration; reduction of taxes, which, incidentally, failed to incorporate a provision reducing tax on physicians who use narcotics in a professional capacity as had been requested; the bonus for war veterans; and reorganization of the consular service on an efficiency basis. This last law, states the writer, might be a good model for the federal personnel engaged in public health work. The child labor amendment to the Constitution, which was passed and submitted to the States, was not accepted by them.

"Although many measures which should have been passed were not, some of those which were not should not have been, so that there was positive accomplishment in their failure." Especially notable in this connection was the defective bill for a new department of education and relief. Another bill for a new department of education with a provision for a huge grant to the states, partly for development of physical education, was also not acted upon. Other bills not acted upon included measures to reorganize the Public Health Service; to grant com-

missions to the sanitary engineers of the Service, which all seem to agree they should have; investigation of medical diploma mills; promotion of rural hygiene; the usual bill for a federal health department; a bureau of medical research; and transfer of the bureau of prohibition.

The second session had about twenty-five more. Of this total number, only a dozen or so were enacted into laws. In the previous Congress there were thirty-one new laws relating directly or indirectly to national health, although this number represented only about 3 per cent. of all the laws adopted by this Congress.

Guy's Hospital Bicentenary.—Guy's Hospital, London, which reaches its two hundredth anniversary this year, owes its origin to the kindly impulse of a sympathetic man, who, in passing over London Bridge, observed a depressed looking person gazing gloomily into the Thames. Thinking the low spirited figure might be poverty stricken and contemplating suicide, the benevolent stranger offered a small coin to the dejected man. But the melancholy man was not in need of money; it was Thomas Guy, who was very rich, but who had found that, after having attained what had been his one aim in life, which was to become wealthy, he had not thus achieved happiness. The kindly act of the passerby brought a new thought into the mind of the unhappy man, who saw in a flash that with money one really can buy happiness—for others. He took steps immediately to establish a hospital, paying for it and for its maintenance, and willing $1,100,000 for its upkeep.—*N. Y. Times.*

Skull Operations Fail as Crime Cure.—Operations on the skull to remove the cause of crime are unwarranted medical practice, in the opinion of Dr. Shepherd I. Franz, an expert in the reeducation of the damaged brain.

The supposition that a bony protuberance of the cranium or some malformation due to accident may press on the brain and be the specific cause of wrongdoing is rejected by Dr. Franz and relegated to the limbo of phrenology or like pseudoscience. Surgeons of questionable ethical standards, with prospects of a high fee, have been willing to operate on a criminal, the purpose in part being to influence a trial court in the direction of leniency. In some cases of this sort the patient, profoundly influenced by so serious an operation on himself, has actually been led to believe that the treatment has cured him. Thus purely by suggestion he deserts the criminal life. To this extent is the cranial operation of value.

Extended experiments in brain operation have convinced Dr. Franz that the upper brain structure works generally as a whole and not in specialized departments. Damage or pressure on one spot does not throw any one faculty alone out of commission, nor does any single faculty or sense belong solely to one unique location. Removal or destruction of a small special brain area will seriously upset the entire mental function, but the patient can be reeducated to perform all his duties with other cerebral material. Upon this assumption immorality or crime tendency is likely to be a feature of the entire cerebrum, and not amenable to surgical operation.—*Science News-Letter,* August 14, 1926.

Origin of the Corset.—The word "corset" was pronounced for the first time in the reign of Charles V; we find it in a work printed in 1510, that is, at the beginning of the sixteenth century; but from the end of the past century they had already been wearing in France corsages tightly laced and trimmed in front, which the ladies wore between their chemises and their dresses. They were generally called *corps piqués* (quilted bodices). Although they were not stiffened with steel braces or whale bones, like the Venetian corsages, the *corps piqués,* if we can believe a gossip of the court of Louis XII, were so tight all the way up that the women could hardly breathe and often suffered great distress when putting them on. The first idea of the corset came when close fitting dresses were in style, dresses *justes au corps.* It was in the reign of Louis VI and his successor, that to improve the figure the idea was conceived of wearing a corsage to mould the form. Under Charles VI ladies used stuffed corsages to simulate full figures, and wore high necked gowns. Isabel de Bavière and, under Charles VII, Agnes Sorel, while reducing their decolletée effects, cramped their waists more and more in their corselets, equipped with steel braces and a *coche* or busk of thin wood in front. In the reign of Henry III appeared the real bodice of whale bone worn by men as well as women. It is said that Catherine de Medici must have imported this style from Italy; for a time it became all the rage. Its results were disastrous. It was at this time that Ambroise Paré, physician of the Hôtel Dieu, showed his pupils on the dissection table the forms of young women whose corsets had so bound, compressed and displaced their vertebræ that they were hunchbacked and miserably emaciated for lack of nutriment. Paré was thus the first doctor who took up arms in the name of health against the corset.—*Translated and abstracted from Aesculape.*

Professional Occupations Do Not Harm Women's Health.—Women factory workers have always received their full quota of medical solicitude, but now the health status of the women in the brain working professions comes in for its share of attention.

Taking a group of school teachers as typical subjects for observation, Dr. Letitia Fairfield, formerly medical director of the Women's Royal Air Force, declares there is no reason to believe the occupation of these women has had any harmful effect on their health. Women, she says, start out in their working careers with slight initial handicaps in the shape of a higher sickness rate in all the diseases than men. They have a liability to a special group of ailments of their own and a tendency to age sooner and more rapidly than men. "Nevertheless," maintains Dr. Fairfield, "my conclusion is that all these handicaps have been exaggerated and can be considerably reduced by improved hygiene." Men have always been more sensible than women in the matter of clothes, exercise and diet, but every year the feminine attitude toward these matters becomes more intelligent. "Without undue optimism," she says, "it seems reasonable to consider that preventive medicine has yet much to contribute to the problem of maintaining the physical efficiency of the professional woman."—*Science News Letter,* September 4, 1926.

Wage Earning Mothers in Philadelphia.—A document of unusual interest and importance to public health has recently appeared in Gwendolyn S. Hughes's *Mothers in Industry,* published by the New Republic Publishing Company. This is a study of 728 wage earning mothers, all of whom had children under sixteen and all of whom were employed outside their homes when the study was made, or had been so employed the year before. The study was begun November 20, 1918, and ended August 28, 1919. In making the canvass, sections largely Hebrew or Italian were omitted because it is not customary for women of these groups to work outside their homes. No colored women were included.

One of the first things revealed by the study was that the work of these women was financially necessary to the upkeep of their families. Statements as to why they had taken up work outside their homes was obtained from 725 of the women, and the following were the reasons given and the number of women so working: Insufficient wages of husband, 208; death of husband, 164; illness of husband, 101; desertion by husband, 94; nonsupport by husband, 79; personal preference, 79. In three fifths of these cases, owing to the husband's illness, death, desertion, or refusal to support the family, there was no income at all from that source, and in nearly one third, the husband's earnings were insufficient for the family upkeep. In eleven per cent. of the cases the mothers took outside work to give their children educational advantages, build a home, etc.

A second feature of the report is the fact that the study showed that the wage earning mother does not cease to be also the homekeeper. She only adds another job to her original one. It might be supposed that this double work for the mother would show in bad effects, health and otherwise, upon the mother herself and her children. This brings us to the medical significance of the report with which we are concerned here. There were 1,352 children living in the homes studied. Of these twenty-three per cent. were being cared for during their mothers' absence, in nurseries or in neighbors' or relatives' homes; seventy-seven per cent. stayed at home, usually in charge of some relative or person living in the same house. The children's health did not seem to have fared badly, the report states. "Health defects seem to be comparatively infrequent among children in these households, since in only 117 (sixteen per cent.) of 728 households was one child or more reported as suffering from a health disability at the time of the visit."

An inquiry into the health of the mothers, exclusive of their maternity experiences, showed that their general record during the time covered by the study was above that of housewives generally. Illness within the past year was reported by forty-four per cent., as against sixty-three per cent. of the housekeepers in a study made in Kensington for a Pennsylvania commission, covering 734 households. The report goes on to say: "Either the wage earning mothers have failed to report all of their illnesses, or they are physically stronger than the women who stay at home. It is probable that women with greater resistance work in industry because they consider themselves physically fit to stand it."

An Effective Remedy *for*
Nervous Sleepless Patients

Neuronidia

Palatable Well-Tolerated Reliable

Allaying Restlessness and Producing Refreshing Sleep

Especially indicated in insomnia from mental strain, neurasthenia and other neuroses; also an excellent sedative in sea-sickness.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Cancer Serum Tests Make Animals Immune.—Cancer serum that has cured cancer in a number of laboratory rats and has rendered them immune to the disease over a long period of time, is the latest cancer news reported by Dr. Thomas Lumsden, working at the Lister Institute, under a grant from the British Empire Cancer Campaign. Dr. Lumsden has been working for several years on the possibility of serum treatment.

In recent experiments he has fought cancer cells with a number of different antisera in an attempt to find out which would be the most effective against the malignant cells, and also in the hope of learning the mechanism by which immunity to cancer is acquired. Fifty rats, all of them with a cancer in each hind foot, were used in one series of tests. Antiserum of a rat or mouse cancer was injected in one foot of each rat. In every case the cancer of the treated foot was cured, and in addition the untreated tumor in the other foot also went away a few days later.

Dr. Lumsden had previously reported that rats treated in this way "were found to be absolutely immune to the tumor concerned." "It is now possible to state," he says, "that this immunity is of long duration. A test inoculation was given to fifty rats six months after their recovery. Of these, only two developed progressive tumors. The other forty-eight were still completely resistant to a cancer which grew rapidly in all of twelve normal animals inoculated with identical material at the same time."

Recent efforts to go further and use serum to fight human cancer are described in a report from Prof. Blumenthal, of the University of Berlin. Prof. Blumenthal long ago proposed that cancer patients might be injected with an extract of the tumor removed by operation, in order that they might become immunized. This method has lately been taken up with success by Dr. Thies, another German scientist, he reports. The chief drawback in this method is that a cancer used for this purpose must not be advanced in decomposition. This means, he says, that only a few operative cancers are adapted to this treatment.—*Science News-Letter,* August 14, 1926.

Increase in Rabies in Dogs.—The City Department of Health considers the prevalence of rabies in dogs in New York as startling, and the increase in the number of dog bites as alarming. In the first six months of this year, 200 of the 395 dogs examined by the Bureau of Laboratories were positive for rabies, while during the first six months of 1925, only twenty-five among the 152 examined were positive. This is the first time in a long period that the number of positive specimens submitted for examination exceeded the number of negatives. Since 1920 there has been a constant increase in the number of persons bitten by dogs from 3,049 to 6,714, and 4,077 persons were bitten in the first half of 1926. There was only one human death from rabies in 1925, and none to date in 1926. The prevalence of rabies among dogs indicates, however, that in every instance in which the condition of the dog responsible for an injury canont be definitely ascertained, prophylactic antirabic treatment should be administered.—*Health News.*

Miscellany.

"How to Deal with the Doctor."—We have reams of advice to the doctor, even entire books, telling him how he should deal with the patient. Mr. Harrison Rhodes, who it seems has written an essay on *How to Be Ill*—which we shall look up later—turns the tables and advises the patient through *Scribner's Magazine* "How to deal with the doctor."

It will be recalled that Smollet has a character indite a letter to his doctor saying, "The pills are good for nothing; I might as well swallow snowballs. . . . Prithee send me another prescription. I am as lame and as much tortured in my limbs as if I was broken on the wheel." Mr. Rhodes confesses to a fellow feeling with the patient. "Many doctors need to be bullied through possibly more patients," he tells us. "It is certain that doctor baiting is a favorite sport with many ill people when they are up to it and have the courage. . . . And yet it is not quite fair. . . . Of course it does not very often come to pitched battles between the doctor and his patient. . . . There are patients who lose much sleep and by working the night nurse hard get their money's worth . . . and it is quite possible that many a fretful invalid rests easier because it has been possible by telephone or otherwise to call to the sick room the doctor from a sound sleep."

"Doctors often know that they are not infallible; in fact it may be guessed that sometimes in their hearts they believe themselves pretty ignorant. But we wretched creatures who call them in are so apt to insist that they shall know everything." But even if the doctor is not omniscient it is pleasanter and no doubt wiser for the patient to believe that "the doctor, or some one, knows it all. At these moments life, if it lasts, should be made more tolerable for the invalid by every flattery, every sacrifice, every lie if necessary—the world owes him that much."

But with convalescence the high comedy appears "with interludes of tenderness, and of real feeling." Old novels are full of this kind of thing, says Mr. Rhodes, citing some of them.

"To those who have a taste for it," says Mr. Rhodes, "there is nothing like sending for the doctor. . . . If a female patient can fall in love with her doctor that will undoubtedly give her great satisfaction and may be strongly advised. That he should fall in love with her is of more uncertain utility; in fact it may be doubted if he will function any better, or indeed quite as well. But she will function better. Perhaps some inner glow, some magic secret metabolism, may transform her to a well woman." This sounds as though Mr. Rhodes had been reading some recent medical literature in which the effect of love in increasing metabolism has been set forth.

While he concedes the morality of the profession he is inclined to the belief that the famous "bedside manner" of the successful practitioner is evidence of his willingness to resort to "the therapy of love," even though it be not mutual.

"The general practitioner, becoming rarer every year should be crowned," thinks Mr. Rhodes, "before

..... Druggist's Name

he passes in a cloud of specialists and odd and slightly illegitimate physicians of all kinds"; a kindly sentiment which the medical profession will applaud, particularly the general practitioner whose career is "sometimes dull but glorious."

Sometimes the doctor, "by the strange clairvoyance which doctors often have, is a great diagnostician, and knows almost at sight of you that your trouble is with the glands in the lobe of the left ear."

"Nothing is more unfair or more irritating to a regular practitioner than to find that his patient is being secretly treated by any of the professedly heretical healers." . . . It is foolish . . . to believe in the newspaper advertisements or the signs on the trees," says Mr. Rhodes.

"At any rate it often really passes the time agreeably to have the doctor in. And it is probable that in the end one does not lose much by cheerfulness."

An Aid to the Medical Practitioner.—Physicians treating venereal disease cases have frequently expressed a need for a pamphlet containing instructions and advice to be given to venereal disease patients. Due to the nature of these diseases and the regimen which proper treatment requires, the need for such a publication has long been apparent. Some time ago the United States Public Health Service prepared a pamphlet known as *Important Confidential Information* expressly for this purpose. The leaflet is in two parts, one dealing with gonorrhea and the other with syphilis. Advice is given among other points on the following: Importance of continuing treatment until cured, proper diet while under treatment, proper care to prevent the spread of the disease, the futility and danger of quacks and self treatment, sex conduct and marriage.

Many physicians have found this publication a valuable aid in securing the cooperation of the patient while under treatment and also as an aid in holding the patient until cured or rendered noninfectious.

The Quarterly Review of Biology.—In commenting on this journal, which is published in Baltimore by Williams and Wilkins Co. and edited by Dr. Raymond Pearl, *The Science News-Letter* for August 7, 1926, says:

Dr. Pearl's new journal occupies a position among scientific periodicals comparable to the *American Mercury* in the realm of regular literature. He has quite apparently determined that his publication shall follow other lines from those of the usual hidebound journal of science. The ground covered spreads beyond the boundaries of the lay conception of the biological sciences into psychology, paleontology, anthropology and geographical distribution, giving much needed correlation to these allied branches. There is an advisory board which consists of men who are the last court of appeal in each of these varied fields, as well as in the different divisions of biology proper.

Readable book reviews, some of them positively entertaining, and a literally priceless Fundamentalist Portrait Gallery are appreciated features out of the ordinary. The *Review* will interest the general reader who rarely ventures to open a professional periodical.

Miscellany.

Philippe Hecquet and the Treatment of Cataract.—In 1862 a surgeon of Turin, Sperino, proposed repeated puncture of the aqueous humor for the treatment of cataract. Such an idea had been put forth more than a century earlier by Hecquet, not only to cure cataracts, but for preventing them, or, according to his own phrase, for dissipating the first thickening. It was in a letter addressed to Silva on March 27, 1729, that Hecquet called attention for the first time to his new method of treatment, which consisted in puncture of the eye to empty the cavities and evacuate the corrupt humors. This letter may be found in the second edition, published in 1730, of the work which Hecquet had published in 1712; namely, *Of the Digestion of Food and of the Maladies of the Stomach, following the System of Trituration or of Pulverization.* It accompanies a reply to Silva on bloodletting, and four letters on revulsion, bloodletting, and kermes-mineral. Hecquet proposed, moreover, to make in the cavities in the eye injections of plantain water, euphrasia, celandine, fennel, flower of camomile, etc.; then he advised recourse after the operation either to internal remedies chosen from among the alkalines or the absorbents, or to local applications of juice of woodlice, of gall of the pike, carp or even man, all methods praised in ancient pharmacopeias, of which Hecquet in this respect received the heritage.—*Aesculape.*

The Colony of St. Fargeau at Ponthierry.—This institution devotes itself entirely to the care and cure, if possible, of paralytics, especially children who have suffered from poliomyelitis. It was founded by a woman all of whose limbs had been paralyzed, but who was cured by the proper care and surroundings. She has devoted her life and her resources to making available to others, especially those who could not afford them, the care and treatment that restored her to a useful and active life.

The colony of St. Fargeau is situated in the country, yet near enough to Paris for visits from that city's leading physicians and surgeons. As much of the reconstruction work as possible is carried on out of doors. The institution is attended by a staff of capable physicians, nurses, and rehabilitation aides, and equipped with the best and latest scientific apparatus, including that for electrotherapy, radiographs, orthopedic correction, and other necessities. A recent report states that nine out of every ten patients leave the institution practically cured. "Many children half crippled upon arrival have gone from the Colony walking easily, without brace or crutch; others, who have been cripples for several years, are walking with crutches or canes, and are improving under their daily lessons in muscular reeducation. Adults who have not walked for years can stand and move about in a fairly normal manner. Some who have come to the institution apparently hopeless cripples, have gone out from it able to live normally, to follow a profession, to build a home, and to have a family."

The Colony is at present inaugurating a campaign to solicit funds for a necessary extension and enlargement of its work. So great has become the number of applicants for admission that many are refused daily. The report states that there is need of more and newer equipment, of a larger staff, and of more visits from the great specialists. The fact that many of the patients are necessarily housed and treated free of charge, or for very small payments, makes the problem of support more difficult. The Board of Directors has estimated that several hundred thousand francs must be secured as soon as possible to ensure the continuance of the work.

Yankee Remedies Not Out of Use.—To the generation that purchases ready made medicine from the corner drug store, ginger tea, suggested as a remedy for President Coolidge when he had a cold, by his father in the wisdom of New England tradition, brings back a whiff of the times when folks dipped their own candles and spun their own cloth. But the days of oldfashioned, homely remedies are not so far gone as that. Several of these have passed even modernism's test, and have taken their places on the drug store's shelves. Among these are castor oil, mustard plaster, rhubarb and soda, and others of like type. Many oldtimers still use oatmeal poultices, sassafras, camomile, saffron and sage tea.

A sty may be driven away, according to early New England beliefs, by rubbing it with a wedding ring, or touching it with a black cat's tail. An old time cure for corns was vinegar and breadcrumbs. Tobacco was good for toothache, juice of dilly flowers for earache. Nosebleed may be stopped by dropping a key down the back, or by tying a cord around the little finger, the left one for the right nostril, and vice versa. Red flannel and a rubbing with goose grease will cure sore throat, and in the early days every good housewife hoarded her goose fat for this purpose. As soon as spring came, she also started mixing sulphur and molasses to give to the family for purifying and nourishing the blood, and so warding off "spring fever."

The principle of vicarious suffering was strong in early times. When a child had fits, the parents would give it a puppy to play and sleep with, expecting the dog to "take on" the child's malady. When the animal died, the child was supposed to be cured. People still may be found who wear a coin around their neck in the belief that it will absorb diseases coming the wearer's way, as evidenced by its turning black. Some rheumatics carry potatoes in their pockets, for, by becoming hard, the potato absorbs the trouble. It used to be customary for elderly women to sleep with a pair of scissors under the pillow "to ward off rheumaticks." An onion in the pocket was said to keep off fits, camphor gum or brimstone would protect from smallpox and other contagious diseases, and so would sulphur bags worn about the neck and sniffed occasionally.

Long ago the public heard the last of the "blue glass craze," but once it was as popular as the modern x ray. In the sixties or seventies, a physician claimed to have discovered that the blue rays of the sun posessed curative powers. Thereupon New Englanders had blue panes put into their windows. Blue windows are still to be found in houses erected half a century ago.—*New York Times.*

English Hospitals for Seamen.—At the opening of the nineteenth century after twenty-five years of intermittent war had brought to Europe a social and commercial distress even greater than it is today, writes Sir James Michelli, C.M.G. (*World's Health,* January, 1926), there were to be found in the streets of London many poor mariners left friendless, homeless and without work. Illness and disease afflicted numbers of them, and there was no provision for the alleviation of their sufferings. In 1818 a small band of philanthropists, among whom was William Wilberforce, conceived a plan for the establishment of a hospital for their relief. Some of these men had been themselves sailors, and so knew that the only way to allay the suspicion of the sailor for hospitals was to have one on a vessel in the Thames. At the end of three years, negotiations secured for this purpose a wooden man of war, the *Grampus,* which was loaned by the Admiralty and fitted up as a hospital from the funds of the new Seamen's Hospital Society.

The *Grampus* was moored in the Thames off Greenwich, since this was the central point of the largest wharves of the port at that time. The lower decks were made into wards, and the top deck covered with a canvas shelter for the convalescents. Furthermore, the society undertook to find jobs for men discharged from hospital, or, if they were suffering from an incurable disease, to arrange for transportation to their own country or district. Particular attention is still paid to this aspect of the work.

In 1821 hospitals were far from being what they are today. The low ceiled wards of the *Grampus* were lit by lamps burning sperm oil and operations had sometimes to be performed by candlelight. The only means of communication with the mainland was by boat, and patients were brought to and from the hospital in row boats and hoisted up a steep gangway onto the deck. One of the old reports reads: "The Captain Superintendent of the vessel presents his compliments to the Committee of Management and regrets that he cannot appear before them owing to the presence of ice in the river." In 1831 a surgeon complained that he had only six nurses to care for 180 beds and the Committee allowed him to engage three more, "with a man for night duty who shall also undertake the work of barber."

In 1832 the Admiralty supplied a larger vessel, the *Dreadnought,* which had taken part in the battle of Trafalgar. In the same year the Seamen's Hospital Society became incorporated under act of Parliament; also a member of Lloyd's, John Lydekker, bequeathed to the Society his entire fortune consisting of a fleet of merchant vessels. At his death these ships were sent for sale throughout the world and this with their cargoes brought a sum of 55,000 pounds sterling. After twenty-five years, the *Dreadnought* gave place to the *Caledonia,* which took over the name, however, of her predecessor. By 1868, although there had been slight progress in hospital care and treatment, it became evident that the hospital must be moved ashore. The ship's decks were found to have all the conditions favorable to the dissemination of infectious diseases. Ventilating facili-

ties were poor, the noise from an adjacent shipyard was very disturbing to both patients and staff, and the accommodations for the nurses precluded the application of the best type from that profession.

So, in 1870, the few remaining pensioners who were inmates of the Royal Hospital, Greenwich, were sent home, and the use of the infirmary of that institution was granted to the Seamen's Hospital Society. The name of Dreadnought was retained for the new hospital, and remains to this day for the building which is still the parent of the corporation. Sir James relates that when he first entered the service of the Society in 1878, he can remember a man who sat at the front door of the hospital on a low stool, on each side of which was a wicker basket. One of these contained the instruments from the operating theatre which were to be cleaned. This was literally performed by "spit and polish," and the second basket returned to the theatre with its load of "cleaned" instruments, to be used in the operations of that day.

In place of one ship or one building, there are now six hospitals and a dispensary under the control of the corporation. All are served by staffs of eminent physicians and surgeons with the latest devices of modern medical science. The Dreadnought Hospital at Greenwich, with 250 beds, the Albert Dock Hospital, with fifty beds, in the midst of the wharves and keys, and the new Tilbury Hospital, with fifty-six beds, serve every port of London. Moreover, seamen come to these hospitals from ports all over the English coast. There are also two institutions for the treatment of special diseases. These are the Hospital for Tropical Diseases, Endsleigh Gardens, Euston, London; and King George's Sanitorium for Sailors, with eighty beds, at Bramshott Place, Liphook, Hampshire, which cares for the tuberculous cases. The society's dispensary in the East India Dock Road, London, is open daily; and high in the Kentish hills is a convalescent home given to the society in 1918 by Mrs. L. G. Angas, whose name it bears. There are resident medical officers at all five hospitals; during the course of the past year, 24,500 patients passed through the society's hands. The Seamen's Hospital Society receives seamen of all nations, creeds, and races, and no sailor is ever asked to pay anything to meet the cost of his illness. The institutions are supported in part by the endowment fund, but most of the funds are supplied by voluntary contributions.

Medical Treatment on the Amazon.—William Montgomery McGovern writes, in his series of special articles in the *New York Times* on his experiences in the Amazon region, of a visit made to him by a tribal medicine man. He was suffering from a slight attack of neuralgia, and, as his own medicine seemed ineffective, he called in one of the tribal doctors, who are also tribal priests. In many cases this important personage rivals or even overshadows the chief. He found that in this region the natives had the same word for jaguar and medicine man. The witch doctors are supposed to take on at night the form of jaguars and to roam the forests.

The medicine man came to the camp and passed his hand over the patient's back and chest for about half an hour, in, apparently, a sort of mesmeric

séance. Then he sucked at the affected area and claimed to be extracting the poison. He then went a few yards away and blew and spat this out, and flung it from his finger tips. By a clever slight of hand he pretended to draw of his patient's neck three black thorns, which, he said, had caused the pain. "I must admit," says the writer, "that after his treatment my neuralgia completely disappeared. Some of these medicine men really have remarkable powers. They are certainly acquainted with many strange herbs and drugs and poisons of the jungle, and seem to know a great deal more than do most Europeans about massage. It is highly probable that they are also possessed of hypnotic powers."

Occupation and Health.—Under this title the International Labor Office of the League of Nations is publishing a series of brochures dealing with hygiene, pathology, and social welfare studied from the point of view of labor, industry and trades, in order to bring together all the information available in various countries concerning industrial processes which may be considered unhealthy. The latest publications deal with anthrax, and the occupations which present the danger of infection thereby, the symptoms, diagnosis, prophylaxis, treatment, and legislative enactments relating to it throughout the world. In similar manner various chemical substances are dealt with, and their manufacture, industrial uses, and effect upon the workers are described. In the majority of cases of anthrax its origin is occupational; but whereas agricultural anthrax, which is by far the commonest form, is due to direct infection from the bacillus and but rarely from the spore, it is pointed out that industrial anthrax is indirectly caused by the spore, rarely by the bacillus.

The diffusion of actinomyces and streptothrix in nature is very wide, these parasites being met with in all kinds of vegetation, in the earth, air, water, dust and in certain foodstuffs such as butter and cheese. Natural infection of man is rather rare if regard is had to the wide distribution of these molds. It does not occur except under certain favorable conditions, such as lesions of the skin or mucous membranes of the intestines, mouth or nostrils; only in the presence of bacteria, inflammatory processes and other special circumstances can it develop pathogenic properties, dental caries providing a specially suitable environment. Its transmission to man from cattle has not yet been decisively proved. Seventy-five per cent. of cases have been said to be occupational in origin; at least fifty per cent. occur in agricultural laborers. The danger of infection is highest during threshing and harvest operations, vegetable dust being the usual and most dangerous vehicle. Actinomycosis is compulsorily notifiable in New Zealand and Dominica only, and it does not occur by name in any list of occupational diseases for which compensation should be paid. The Industrial Committee of California, however, has awarded compensation, as an accident, in one case affecting a workman engaged in putting corn into sacks, and might be awarded in other countries where "infection due to dust" is recognized as cause for compensation.—*Medical Press,* October 6, 1926.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Maternal Mortality and Morbidity.—A national program for the prevention of maternal mortality and morbidity throughout the United States is outlined by the Children's Bureau of the United States Department of Labor in a report on maternal mortality recently made public.

This report, the work of Dr. Robert Morse Woodbury, formerly director of statistical research for the Children's Bureau, brings together and analyzes all available material, both American and foreign, on deaths of mothers during childbirth.

Maternal mortality rates in the United States are today among the highest in the civilized world, and but a slight decrease in these rates has occurred since the beginning of the present century, Dr. Woodbury's report states. The significance of these facts from a national point of view is found not only in the loss which this means of the lives of women presumably at their prime, but also in the farreaching effect of maternal mortality on the infant death rate.

Dr. Woodbury estimates the total number of maternal deaths in the United States on the basis of 1921 birth registration area statistics to be 18,281. However, a careful survey of sources of error in certifications of death throughout the area leads him to the conclusion that the true number of maternal deaths is probably as much as 12 per cent. in excess of those reported, making an estimated yearly death toll of more than 20,000 women. The maternal mortality rate in 1921 was 6.8 per 1000 live births. The provisional 1924 rate was 6.6.

Figures showing the trend of maternal mortality over a twenty-two year period in the United States, if accepted at their face value, would show an increase in the maternal death rate from 13.3 per 100,000 population in 1900 to 16.9 in 1921, according to the report. However, analysis of various factors affecting these statistics, particularly the campaign for better certification of the causes of death during recent years, would indicate in reality a "very slightly downward trend" since 1900.

Comparison of the United States rates with those of other countries shows that the United States ranks among those having the highest rates, such as New Zealand and Chile. Among the countries having rates less than half that of the United States are Denmark, Finland, Italy, Japan, the Netherlands, Norway, Sweden, and Uruguay.

Analysis of the causes of maternal deaths in this country shows that the most important single cause is puerperal septicemia, due to infection resulting from lack of surgical cleanliness and almost one hundred per cent. preventable through careful asepsis. Two fifths of the maternal deaths in the death registration area of 1921 were due to septicemia. Among other causes, puerperal albuminuria and convulsions were most important, contributing over one fourth of the deaths. This cause is preventable through competent medical care during the prenatal and confinement period. Other causes of death included accidents of pregnancy, hemorrhage, accidents of labor.

Other puerperal causes of death may be prevented in a large proportion of cases by proper prenatal and natal care of the mother. Studies in this country, including the demonstration in New York City of the Maternity Centre Association and the Henry Street Settlement, as well as evidence of physicians and public health authorities here and abroad, have shown the value of competent medical supervision in the reduction of rates from these causes.

The preventive program suggested by the report, in its main outline, is as follows:

1. Regulation of the practice of obstetrics, by requiring a license to practise from both physicians and midwives, by establishing minimum requirements for obtaining such a license, and by defining and prescribing penalties for malpractice.
2. Regulation of public and private hospitals and maternity homes through legal provisions governing the establishment of such institutions and requiring that they be licensed and subject to inspection.
3. Legislation for the control of venereal diseases including the making of these diseases reportable.
4. Requiring that puerperal septicemia be made reportable, as is now the case in a number of states.
5. Provision through Governmental or public sources of better facilities for training medical and nursing personnel and more adequate clinics, hospitals, and maternity homes.
6. Subsidies in aid of State or local activities by Federal or State governments, as in the United States during the past four years through the Maternity and Infancy Act.
7. Educational work directed toward informing mothers of the need of adequate maternity care.

Miscellany.

Dr. Abernethy and "My Book."—Saint Bartholomew's Hospital occupies a chief place in the annals of the medical charities of London. It is one of the five Royal Hospitals. It was originally founded in the twelfth century by Rahere, and a second foundation on letters patent took place in 1544. From that time to the present there has been connected with it a succession of men whose names are familiar to us as household words. At the commencement of this second period of its history there was Thomas Vicary, whose *Englishman's Treasure,* a work on human anatomy, was extensively circulated. Among the others were William Harvey, John Woodall, Percivall Pott, John Freake, and John Abernethy. The most important fact associated with Abernethy was the inauguration by him of the third period in the history of this famous foundation. We are told that he may "justly be looked upon as one of the great reformers and teachers of the medical profession." He was trained at St. Bartholomew's, and was a pupil of Charles Blicke and John Hunter. He became an assistant surgeon, and as such he gave lectures in his own house in Bartholomew Close. These lectures were so successful that the governors were induced to build a regular lecture theatre to accommodate Abernethy's students. In this way Abernethy became the founder of the now world famed medical school of St. Bartholomew's.

Abernethy can have had no qualms about getting himself talked about or of extending the circulation of his book. *My Book,* as he called it, was his *Surgical Observations on the Constitutional Origin and Treatment of Local Diseases,* which became very popular. There are many anecdotes told of his eccentricities of speech and behavior; many of these are undoubtedly apocryphal; but one of the best, which bears evidence of being tinctured with Abernethy's genius, is told by Theodore Hook about this book.

"The door was thrown open," writes Hook about the visit to Abernethy, "with a jerk so sudden that I involuntarily jumped off my chair and salaamed to the little man. . . . When he had, as I fancied, looked clean through me with his piercing grey eyes he sat down, and I thought it high time to follow his example. . . . he opened in a short, sharp bark, half growl, 'Well! what the d—— do you want?' 'Physic.' 'What's the matter with you?' 'Can't tell; read too much, I think.' 'Where do you come from?' 'Oxford.' 'Ah! drink too much, you mean. Never knew an Oxford or Cambridge man die from over-application to anything but his stomach. What the d—— did you come to me for?' 'To be cured.' . . . 'There, hold your tongue; put it out and let me see it. That will do—put it in again—shut your mouth, and keep it shut.' He wrote on a bit of paper about the size of a crown piece a prescription for my disorder, and told me to go to Paternoster Row and buy his book of Longman & Co.; to turn to page 72, and follow his printed rules as closely as I could; but if possible to go down to the seaside for a time, and enter into every scene of gaiety and amusement."

No Time to Get a Pulmotor!
Something Must Be Done at Once! But What?

These are some of the exclamations which greet the physician called to the victims of gas poisoning. The big question is—Has he a supply of

ALPHA-LOBELIN

INGELHEIM

If he comes so armed his first act will be to inject intramuscularly the contents of an ampule. This conserves the time required to move the victims into frēsh air and, if necessary, protect them from cold. Often by the time this is accomplished Alpha-Lobelin has done its work and normal respiration has been re-established. Should further stimulation be required another injection can be made without fear of untoward effect as Alpha-Lobelin is non-cumulative and non-toxic.

Head Wounds, Face Wounds, Neck Wounds

—of small size—

are safely, quickly and neatly dressed with Band-Aid Protective Dressing. This consists of a 1½-inch square pad of sterilized gauze already fixed in the center of a strip of Z-O Adhesive Plaster.

Where the wound is long and narrow, two or more of these handy dressings may be placed in a continuous series.

If aeration is desired, the gauze pad may be applied in an arched manner; the perforations in the back will be found to favor this object.

Fastidious patients like this dressing.

Band-Aid Protective Dressing often affords a more satisfactory dressing for these wounds than does a bandage. It is quicker in application, easier in replacement, and better in appearance.

Physicians may order from drug stores, or write for samples to Johnson & Johnson.

A Directory of Tuberculosis Institutions.—An up to the minute directory and book of information about tuberculosis institutions serving New York City and the procedure necessary to obtain admissions to them has just been published by the Tuberculosis Sanatorium Conference of Metropolitan New York.

It is the first booklet of its kind published since 1915 when the Department of Health issued a similar one. It is designed especially to be helpful to physicians, nurses, clinic workers and others interested in tuberculosis work in New York City. Copies are available free, upon request, to all physicians in the greater city of New York. Agencies and all others who are interested may secure them at cost price—thirty cents a copy.

Frederic D. Bell, secretary of Hospital Service, New York Tuberculosis and Health Association, is chairman of the committee which compiled the booklet. Other members are Dr. Fernand D'Orbessan, resident physican St. Anthony's Hospital; Jacob Goodfriend, assistant superintendent Montefiore Hospital; Dr. Gez Kremer, medical superintendent, Sea View Hospital; and Sterling Potter, superintendent Hospital Admission Bureau.

Those in Manhattan and the Bronx who desire copies may secure them from the New York Tuberculosis and Health Association, 244 Madison Avenue, New York City; in Brooklyn from the Brooklyn Tuberculosis and Health Association, 67 Schermerhorn Street, and in Queens from the Queensboro Tuberculosis and Health Association, 163-18 Jamaica Avenue, Jamaica.

(Formula Dr. John P. Gray)

IF you wish the latest data on contagious affections, send for a copy of *"The Notifiable Diseases."* Free on request.

in acute and chronic affections of the air passages, shows the soundness of the therapeutic principle—"treat the patient as well as the disease." The effect of Gray's Glycerine Tonic Comp. on the nutrition is soon apparent; the patient **eats better, sleeps better,** and **feels better**—and as his condition improves, his cough and other symptoms disappear. Best of all, they do not return, for his recovery is only the logical sequence of increased vitality and resistance.

Valentine's Meat-Juice

For **Quieting** the **Irritable Stomach** in **Pregnancy,** for **Rapidly Restoring** the **Vital Forces** in **Hemorrhage,** for **Sustaining** and **Strengthening** in **Long** and **Exhausting Labor, Valentine's Meat-Juice** is extensively employed in

Obstetrical Practice.

Dr. E. Duloroy, *Physician Accoucher to the International Hospital, Paris, France:* "A young accouchée, in a very weak condition and suffering from stomach trouble, could retain no food, but was able to assimilate VALENTINE'S MEAT-JUICE given at first in small doses. An improvement was quickly visible, the patient recovered her strength and is today in good health."

Dr. Javier Ortis y Ferrer, *Physician to the Municipal Charity of Madrid, Spain:* "VALENTINE'S MEAT-JUICE has given the happiest results in cases of debility in the asthenia produced by operations of confinements. In some cases of Tuberculosis it restored exhausted strength, and in every case where organic exhaustion manifested itself as an effect of disease."

Physicians are invited to send for brochures containing clinical reports.

For Sale by American and European Chemists and Druggists.

Miscellany.

When the Medical Profession of New York Paid Homage to "the Autocrat of the Breakfast Table."—Early in 1883, at a dinner party of physicians at the University Club, New York, one of the number alluded to the fact that Professor Oliver Wendell Holmes had just given up his chair in the Medical Department of Harvard University. The question came up as to whether, at this time, it would not be a graceful and appropriate expression of the sentiment of the medical profession of the city of New York to invite Dr. Holmes to a public dinner, so that all classes of the profession, regardless of school or affiliation, could join to make such a demonstration a happy as well as a useful one.

The suggestion was received by all present with great enthusiasm, and an organization was immediately effected as a nucleus for the formation of a general committee of arrangement. Dr. T. Gaillard Thomas was elected chairman; the committee members were Fordyce Barker, William T. Bull, Clement Cleveland, John G. Curtis, John C. Dalton, Francis Delafield, William H. Draper, Frank P. Foster, Allan McLane Hamilton, Edward L. Keyes, Francis P. Kinnicut, Alfred L. Loomis, Charles McBurney, Henry G. Piffard, William M. Polk, Beverley Robinson, David St. John Roosa, both Smiths, Lewis A. Stimson, and Robert F. Weir. Among invited guests were James Anderson, Alonzo Clark, Alfred C. Post, William H. Van Buren. Guests from other cities included Henry J. Bigelow, John S. Billings, Samuel D. Gross, A. Weir Mitchell, William Pepper, John V. Shoemaker. Bishop T. M. Clark represented the clergy, the Hon. William M. Evarts the bar, George William Curtis literature, and Whitelaw Reid the press. Charles A. Dana of the *Sun* and Horace White of the *Post* also were invited. Besides these there were many others, both subscribers and guests, whose names are now famous.

The dinner was given on April 12th at Delmonico's, then at the corner of Fifth Avenue and Fourteenth Street. The menu was printed in book form bound heavily in plush of various colors. The covers were ornamented with a gilt design consisting of scalpel and pen crossing each other, and encircled by a laurel wreath. Stubbs' orchestra played popular airs in the gallery. Mr. Delmonico himself took personal charge of all the details of the dinner, and spared no effort or expense. Dr. Fordyce Barker, president of the Academy of Medicine, then at 18 West Thirty-first Street, was master of ceremonies. While coffee was being poured, special messengers hurried through the room distributing to each guest what purported to be a telegram from Boston dated April 1, 1883, with a pen and ink caricature on one side, and a poem of acceptance on the other, both done by the hand of Holmes himself. "Then came the intellectual part of the feast. For thirty-two successive years, the versatile Professor had written annual poems for his class of 1829, so that he found it not at all difficult to respond to the assembled doctors with a fitting poem of over two thousand words. Although hastily composed, it was in perfect rhyme and meter, fitting the occasion, full of apt puns and humorous thrusts." At the close of the toasts, William T. Bull, at that time not yet afflicted with cancer of the throat, which was later to cause his death, led the singing of Auld Lang Syne with his beautiful baritone voice. The souvenirs of the occasion were sherbet cups, in the form of miniature skulls.

The tribute to Holmes in the toast of George William Curtis elicited much applause when he said: "But mark his own impartiality: while he professes medicine, he practises literature; while he cools the fever that wastes the body, he kindles the fires that ennoble the soul; and, soothing mortal pain with cunning anodyne, he distills an immortal joy from the divine nepenthe of song."—*Abstracted from Notes and Abstracts.*

"Father Craft" and Child Welfare.—It is not recognized generally that although in the rearing of a child most depends upon the mother that the father has some say and influence in the matter. Occasionally he objects to certain phases of the child welfare movement as, for instance, to the visits of health visitors. The working man is jealous of his rights and resents frequently the intrusion of health visitors albeit they come with the best intentions.

At the English Speaking Conference on Maternity and Health Welfare held recently in London, Dr. James Fenton read a paper on the above subject. He pointed out that they had been concentrating on education of mothers in mothercraft. They were apt to forget the father who was a factor they could not ignore. He was still the head of the house in most working class homes and often prejudiced the mother against accepting the rational advice she received from trained maternity and child welfare centres. Again, many fathers were likely to regard health visitors as busybodies. Moreover, they were inclined to regard the infant welfare centre as a kind of club for mothers, and while they saw no objection to visiting their own clubs, they thought the mother's place was in the home, especially if she had young children. Dr. Fenton recommended a plan to overcome this difficulty, put into practice by himself, that of inviting the objecting husbands in small groups to meet him at the infant welfare centres in the evenings. It was found that many of the fathers became interested, and nearly all withdrew their opposition when once the facts were clearly stated. Subsequently he offered to address the fathers on subjects chosen by themselves. Those which seemed most popular were cancer and vaccination. After a little encouragement the men not only asked questions, but entered freely into the discussions which followed. Dr. Fenton went on to describe how a small group of men in his district had decided to form a Fathers' Council, the first body of this kind to be established in Great Britain. This council had its own publicity man who wrote articles for the local press. The articles which appeared proved a wonderful stimulus to the fathers who were flattered by a little publicity.

In preaching the gospel of personal and domestic hygiene, the public must be educated in their methods and the best modes of carrying them out. In order to do this successfully both mothers and fathers must be interested. Fathers' Councils, therefore, are important steps in the war against disease.

Sheik Abou Ali el-Hosein Abd Allah Ibn Sina.—Above appears the full name of the Arabian physician known to western civilization as Avicenna. He was born in 980 A.D. near Bokhara, where he became known as a youthful prodigy, having before the age of ten committed to memory the Koran and most of the Arabic poetry extant. In a brief autobiography reproduced by Post Sargent in the *Adventure* he tells of his wanderings through Arabia and Persia. In Teheran he settled down for a while and "wrote some thirty treatises, my wisdom being by then ripened." Journeying to Hamadan, where Shems Addaula was Emir, by him he was made court physician and Vizier and loaded with riches. But the Emir being defeated in an attempt to subjugate a neighboring ruler the populace turned against Avicenna, on the ground that he had advised against the expedition and had used his magic to cause its defeat. Robbed of his fortune and barely escaping with his life, he eventually made his way to Thabaristan, where he was received with honors by the ruler of Ispahan, Ala ed-Daoulah. Here he abode for many years with peace and honor. "Many disciples came to Ispahan to hear my words and learn the true science of human flesh and blood, as expounded by Galen and Hippocrates and Ibn Sina [Avicenna]. From Bokhara, and Teheran and Tabriz; from Stamboul and the cities of the Grand Mogul; from the far towns of infidel lands they come. And depart not with unfilled minds."

The fame of Avicenna spread throughout the western world and his teachings were followed until the modern era of medicine set in. At least one of his *obiter dicta* has come to naught, for he said: "The air and the clouds are to the winged creatures, and of these will man never never be, for who will give him wings to fly?"

Belgium, the Classical Land for Ophthalmology.—At the recent Ophthalmological Congress held at Brussels, Professor Lapersonne delivered an address entitled Belgium, the Classical Land for Ophthalmology, giving significant examples in support of his theory. "To cite only a few," he said, "since the beginning of the eighteenth century, in this renaissance of ophthalmology, which has realized in our profession the greatest advances since the school of Alexandria, we have Brisseau, stating before the Academy of Science of Paris that 'cataract is formed by the opacification of the crystalline lens.' And we all remember the touching ceremony at which, at the summons of our regretted colleague, Van Duyse, we united to glorify the memory of the precursor of Daviel.

In the nineteenth century there began in Belgium the great struggle against granular ophthalmia, brought from Egypt by the armies of Bonaparte, which was nothing else than trachoma, made more acute and more destructive by what we call today infectious associations. With this struggle we associate the glorious names of Kluyskens, Vleminck, Van Mons, Fallot, and later Hairion. The last pursued to a high degree the study of the pathological anatomy of trachoma, affirmed its contagious nature, and proposed the best prophylactic measures to combat this dangerous malady."—*Translated from Aesculape.*

"Keep the Child in School"

Ordinarily the child contracting Whooping Cough at this season of the year will be in ill health until Spring. All Winter he will be sensitive to changes of weather and susceptible to whatever infections may be prevalent. Interference with nutrition is certain and growth is thus retarded. If the child is of school age, enforced absence may be so protracted as to necessitate a review of the work of the entire year. Respiratory complications may prove serious or even fatal.

DIATUSSIN

Given early often aborts the attack or if continued throughout the course of the disease prevents much suffering and the development of serious complications.

A safe concentrated product given in drop doses. Contains no opiates or bromides. Not in a bulky, syrupy vehicle.

ERNST BISCHOFF CO., INC.
133 Hudson Street
New York

Simply pin this to your letterhead and a sufficient amount of DIATUSSIN for clinical trial will be forthcoming.

In recommending an infant food —consider its nutritive value first

Cleanliness, digestibility, and palatability are also of importance, but without nutritive value any food would be useless as a body builder.

FOR the infant, breast milk furnishes all of the requirements mentioned. There is no need to seek further for a better food because no one has as yet been able to prepare a formula which can be considered anything other than a second choice.

As a breast milk substitute there is no better food for the infant than Eagle Brand Milk. For more than four years the largest child-feeding clinic in the history of the world has been maintained in the Near East, and Eagle Brand Milk has met every requirement for a complete milk food for the infants and older children throughout this period.

Reprints of clinical experiments with sweetened condensed milk will be sent upon request.

Medical Service with the French Army.—Colonel Bailey, K. Ashford, M.C., publishes in the November issue of the *Military Surgeon* an interesting paper based on his experience when serving with the French Army. In the course of the paper the organization of the French Medical Service is given in considerable detail. The important rôle assigned to the pharmacist in the medical service of the French Army is in notable contrast to conditions in the United States Army.

First Aid for Poison Gas Patients.—The Medical Research Division of the Medical Corps at Edgewood Arsenal, Maryland, offers a series of suggestions as a guide for first aid treatment. Quick action is essential, delay may prove fatal. In all cases the patient must have fresh air, rest, warmth, careful attention and neutralization of the chemical. The patient should, 1, be removed from the gas infected area; 2, all gas infected clothing removed; 3, washed with water to remove gas or chemical; 4, sent to aid station by ambulance; 5, kept silent in reclining position; 6, any areas burned by phosphorus must be kept under water. *This is very important.* The poison gases may be roughly divided into tear gases, the chlorine group and the mustard group, though this division is not clearly defined. In most of the tear gases the effects are largely confined to lachrymation and are not prolonged. The cyanide tear gases are, however, very toxic. These should be treated by washing with sodium bicarbonate solution and boric acid solution, followed by hypochlorate solution twenty per cent.

The chlorine group of poison gases includes several containing arsenical compounds. They affect the lungs particularly and, therefore, are toxic as well as locally irritating. For these wash exposed surfaces with sodium bicarbonate and sodium hypochlorate solution. Give with a cream, spray throat with alcohol, and give light stimulant or coffee from time to time and give oxygen. The mustard gas group should be washed with organic solvent such as benzene, chloroform or either, followed by soap and water or hypochlorate and bicarbonate solution. Carbon monoxide cases should be treated with oxygen inhalations. Further details appear in the *Military Surgeon* for November.

Blood Tests for Paternity.—Recent work on the blood groups has increased the interest in the medicolegal applications in cases of disputed parentage. Ottenberg's tables, which have been the standard in such cases, are based on the assumption that the blood groups are inherited as two independent pairs of mendelian unit factors. Recently, however, it has been shown that the blood groups are inherited as a series of three multiple allelomorphs. This hypothesis was suggested independently by Bernstein in Germany and Furuhata in Japan. It was immediately confirmed by Snyder in the United States, and has been accepted by most of the blood workers of the world. This hypothesis does not invalidate any of the previous tests, but makes the application even more close. These tests for paternity can be made by any one capable of performing an accurate agglutination test, regardless of his personal knowledge of the principles of heredity. —*Jour. A. M. A.,* November 27, 1926.

Calcium and Phosphorus

The profound physiologic importance of calcium and phosphorus, especially in the so-called wasting diseases, is becoming increasingly evident, and the best form of calcium and phosphorus for administration is unquestionably calcium glycerophosphate.

ESKAY'S NEURO PHOSPHATES

contains calcium and phosphorus in the form of glycerophosphate, is rapidly absorbed and does not cause gastrointestinal irritation on long-continued use, as do the usual calcium salts.

Acidosis and Public Health

The responsibilities of the physician in relation to community health are constantly broadening. Safeguarding health is a grave responsibility and it necessarily includes the education of people of all classes in the prevention of disease. The medical practitioner of today considers not only the disease of the moment but looks to the future welfare of his patient.

Acidosis is the forerunner of such serious organic troubles that it should properly receive increasing consideration from the medical profession in its work of disease prevention and life extension.

Furthermore gastric hyperacidity, acidity of the mouth, and other of the more obvious manifestations of acidosis are so frequently first observed incident to other conditions that the simple corrective treatment here discussed should be kept in mind as a wholesome routine for a considerable percentage of patients.

Gastric hyperacidity, acidity of the mouth and other of the more obvious manifestations of acidosis are promptly counteracted by Phillips' Milk of Magnesia which has a pronounced affinity for acids, the harmless resultant compounds being readily excreted.

The increasing use of sodium bicarbonate by the public to control "acid stomach" should be considered in this connection. Only a part of the bicarbonate is effective and that portion which produces carbon dioxide may be seriously detrimental.

Phillips' Milk of Magnesia being free from carbonates does not distend the stomach nor cause flatulence of the lower intestinal tract. Its antacid action is pronounced. A given quantity of Phillips' Milk of Magnesia neutralizes almost three times as much acid as a saturated solution of sodium bicarbonate and nearly fifty times as much as lime water. Further it has the additional merit of being laxative, a quality of importance here since constipation is so frequently the underlying cause of hyperacidity.

DOSAGE

The usual dose of Phillips' Milk of Magnesia, as an antacid, ranges from one teaspoonful (4 c. c.) to one tablespoonful (16 c. c.) This amount should be mixed with an equal portion of cold water or milk and given half an hour after meals.

For its laxative effect, the adult dose is one to two fluid ounces (30 to 60 c. c.). The aperient action may be facilitated by giving the juice of lemon, lime or orange, half an hour thereafter.

PHILLIPS' Milk of Magnesia

CAUTION. Beware of imitations of Phillips' Milk of Magnesia. Kindly prescribe in original 4-ounce (25c bottles) and 12-ounce (50c bottles) obtainable from druggists everywhere.

"Milk of Magnesia" has been the U. S. Registered Trade Mark of The Charles H. Phillips Chemical Co. and its predecessor Charles H. Phillips since 1875.

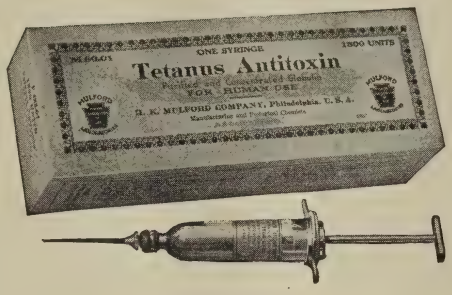
Deservedly popular!



Mulford Tetanus Antitoxin

Increasing sales have more than kept pace with the growing practice of immunizing accident and surgical cases against tetanus, as a routine matter.

The reasons are—

High Concentration
Low Total Solids
Clarity of Product
Isotonicity with Blood
Liberal Excess in each Dose
Perfected Syringe Container

Instantly available from all Mulford Branches and Depots and sold by good druggists everywhere.

Supplied in doses of

1500 UNITS
5000 UNITS
10,000 UNITS

Mulford Antistreptococcic Serum Polyvalent

Polyvalency

Antistreptococcic Serum Polyvalent–Mulford, is a highly polyvalent serum from the blood of horses which have been immunized against representative strains comprising both hemolytic and non-hemolytic streptococci.

Standardization

Antistreptococcic Serum Polyvalent–Mulford, is standardized by the agglutination method. By maintaining a fixed standard, Mulford Antistreptococcic Serum Polyvalent has agglutinated every strain of the streptococcus tested in the Mulford Biological Laboratories.

Uses

Antistreptococcic Serum is indicated in erysipelas, septicemia, pyemia, sapremia due to streptococcic infection, streptococcic pneumonia and the streptococcic complications in pneumonia, in puerperal sepsis, in pyemia and septicemia conditions in which the streptococcus is known to be the offending organism.

Dosage

Kolmer points out that in true streptococcal infections, the cocci are likely at some time to be found in the blood stream. "As in the serum treatment of pneumonia, at least 100 cc of serum should be given intravenously and the dose repeated if necessary."

How Supplied

ANTISTREPTOCOCCIC SERUM POLYVALENT

In packages containing one syringe of 20 cc.

In packages containing one double-end vial of 50 cc for intravenous injection.

ENGELN

X-RAY

The New Engeln Fluoroscopic Unit

FOR your own personal satisfaction in those difficult cases, you have often wished for the certain and positive diagnosis which the X-Ray affords. It is now possible for you to fulfill this desire with a full capacity equipment for all of your Fluoroscopic examinations and a large part of your Radiographic work. This unit will fit into the available space in your office, and best of all, it can be secured at the price and terms which will suit your income. This new and complete X-Ray unit for diagnostic work occupies a floor space only 23″x 26″, has a sturdy 5″ 30 milliampere transformer, a new type of overload relay or safety switch, milliampere meter and volt meter with soft indirect illumination and all of the ease of operation, quality, dependability and advanced design for which Engeln equipment is famous. One of the booklets describing this new unit has been set aside for you—tell us you want it!

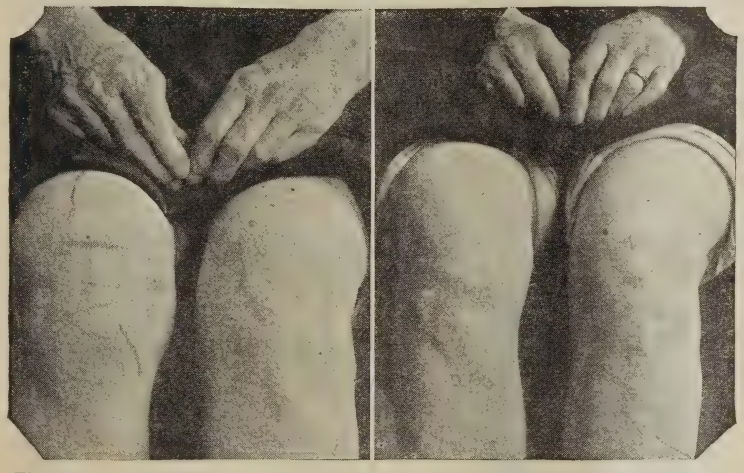
RHEUMATISM URATIC DEPOSITS & ARTHRITIS

AND EFFECTIVE REMEDIES

BEFSAL
"REG. U. S. PAT. OFF."
is a synthetic organic chemical compound of the benzyl-ethyl-formaldehyde-salicyl and cinchoninic acid radicals.

PYR-AZO-PHEN
"REG. U. S. PAT. OFF."
is a Diethyl-Benzylidene Hydroxy-azo-Benzol-Methylene Disalicylic-Dicinchoninic Acid.

This radiograph, taken after three months' treatment, shows that the destruction of the cartilages had begun and from the influence of this bactericide was stopped.



This photo was taken in March, 1923, after 3 months' treatment, showing exudate of knees reduced and wrists almost restored to normal.

This photo was taken in April, 1924, showing furthur absorption of exudate of knees with wrists and fingers restored to normal.

These photos partly show the value of BEFSAL in arresting a case of rheumatoid arthritis and correcting structural damage.

There had been progressive involvement, for 15 months previous to this treatment, of the wrists and knees, these joints having become much enlarged, very painful and almost immovable, and the case pronounced hopeless by eminent physicians.

These products are scavengers for removing effete products from the system—increasing the elimination of urea 2% and 3% without any undue irritation to the animal tissues or unduly depressing effects upon the heart or of a disturbing action on the physiological integrity of the blood. They possess marked internal antiseptic value. In sufficient dosage are more of a specific in acute rheumatism than is quinine in malaria.

"The arthritis and neutritis of left arm, of my rheumatoid arthritis case, is growing less, in fact, there is very little left of either now. Some stiffness in one shoulder about all that is left of the arthritis. The flexion of the fingers of both hands is now nearly perfect, where before she could only partially close the hands. At first she could not reach her head with her hands, but now she can "do her hair." She was taken ill about three years ago. A chronic eczema which troubled her for years and years has entirely disappeared. She walks and acts like a person who had never heard of arthritis. And she surely has an appreciation of befsal and pyr-azo-phen."—California Physician.

"Mrs. T., aged 50 years, had suffered 6 years from multiple rheumatoid arthritis, which started in the little finger of the right hand and gradually extended to every joint in the body, excepting the hips. The knees and elbows became bent and two years ago patient had to give up walking, as it was too painful. In 1919 patient had her tonsils and every tooth removed and x-rays taken of every part of the body to learn the source of infection. The doctor said he could find nothing to cause the trouble. She underwent the regular curriculum of treatments without avail. Four months ago the patient began taking befsal dosage of 120 to 180 grains per day, totaling 36 ounces. The medicine at first seemed to act as an astringent, but now the bowels move freely. The middle joints of most of her fingers seem to be ankylosed, but all the other joints of her body move, and she now walks. She is certainly feeling better, with improved general health and greater freedom of action."—Medical World.

Invented and Manufactured by Dr. S. LEWIS SUMMERS, Ambler, Penna.

The Natural Habitus of Regular Bowel Action

is seldom restored by ordinary laxatives. But the effects of Agarol are not those of ordinary laxatives. To be sure, it will clear out the bowel thoroughly and well, without griping or distress, and often afford prompt relief when other measures have failed.

But it is when it is employed regularly for a reasonable period, that Agarol demonstrates its superiority. For example, of 400 cases of all forms of constipation treated in a New York hospital, not only were the results uniformly satisfactory, but *a large percentage had the natural activity of their bowels re-established in two to four weeks.*

Agarol enables the physician to treat chronic constipation with new-born confidence.

AGAROL, the *original* Mineral Oil—Agar-Agar Emulsion, has these special advantages:

Perfect emulsification; stability; pleasant taste without artificial flavoring.

Freedom from sugar, alkalies and alcohol; no contraindications; no oil leakage.

No griping or pain; no nausea or gastric disturbances; not habit forming.

As a Preventive—

as an aid in treatment

Physicians suggest this sustained oral antiseptic

Endorsed by physicians everywhere

IN their educational work to reduce the prevalence of throat infections in Winter, more and more physicians are using and suggesting Formamint. They know that the action of this germicide is effective—and, what is equally important, that it is sustained. The palatable Formamint tablets can be taken anywhere, at any time infection is likely to occur.

Likewise, in the treatment of throat infections already contracted the medical profession is finding Formamint valuable in a variety of cases, and often superior to necessarily intermittent and inconvenient gargles and sprays.

Formamint is safe and non-irritant. We believe it fills a unique place as a convenient and dependable oral antiseptic with the profession. We shall be glad to place at the disposal of any member of the medical profession enough samples for a thorough test. Address the Bauer Chemical Company, Dept. E-11, 113 West 18th Street, New York City.

Formamint

GERM-KILLING THROAT TABLETS

IODIN

The Management of an Infant's Diet

Malnutrition, Marasmus, Infantile Atrophy, Athrepsia

In an endeavor to improve conditions that may be properly grouped under the above-mentioned terms, the first thought of the attending physician is an immediate gain in weight, and the second thought is to so arrange the diet that this initial gain will be sustained and progressive gain be established. Every few ounces gained means progress not only in the upward swing of the weight curve, but in digestive capacity in thus clearing the way for an increasing intake of food material. As a starting point to carry out this entirely rational idea, the following formula is suggested:

Mellin's Food	**8 level tablespoonfuls**
Skimmed Milk	**9 fluidounces**
Water	**15 ounces**

This mixture furnishes over 56 grams of carbohydrates in a form readily assimilated and thus quickly available for creating and sustaining heat and energy. The mixture supplies over 15 grams of proteins for depleted tissues and new growth, together with over 4 grams of inorganic elements which are necessary in all metabolic processes. These food elements are to be increased in quantity and in amount of intake as rapidly as continued improvement is shown and ability to take additional nourishment is indicated. Suggestions for this readjustment are set forth in a clear manner in a pamphlet devoted exclusively to the subject, which will be sent to physicians upon their request.

Continued repetition of highly successful and oftentimes remarkable results from the application of this procedure justifies its universal recognition.

Mellin's Food Co., 177 State Street Boston, Mass.

For COUGHS and BRONCHIAL AFFECTIONS

Prescribe

ANGIER'S EMULSION

Prompt, pronounced relief results from the naturally demulcent, expectorant, antiphlogistic properties of Angier's Emulsion. It assuages the irritation, induces expectoration, eases respiration and relieves congestion. The perfectly emulsified oil maintains proper elimination and enables the Emulsion to exercise the benefits of its bland tonic effects on the whole system.

If you would like to try some samples, we will send them, charges prepaid, on request.

ANGIER CHEMICAL COMPANY

GONOLIN

REG. U. S. PATENT OFFICE

The Proto-Enzyme Treatment for Gonorrhea

In What Respect Does Gonolin Differ From Other Protein Substances?

TYPICAL CASE REPORTS

Initials of patient: J. M. Age 50. Male. Type of Infection: Chronic. Case History: Infection of three years' standing. Small discharge continued. Muscles and joints affected. Previous Treatments: Various treatments tried without effect. Serological Findings: Positive for Gonococci. Length of GONOLIN Treatment: One month. Began May 15, 1926; finished June 15, 1926. Total Injections: 12. End Results: Discharge stopped. Patient much improved, felt much better. Dated: Aug. 14, 1926. Signed: Dr. C. I. T., Detroit, Mich.

Initials of patient: A. E. Age 28. Male. Type of Infection: Acute. Case History: Acute gonorrheal urethritis. Previous Treatments: None. Length of GONOLIN Treatment: 7 weeks. Began Nov. 26, 1925; finished Jan. 15, 1926. Total Injections: 27. End Results: Negative. Remarks: Very satisfactory. Dated: Aug. 10, 1928. Signed: Dr. E. H. H., N. Y. C.

Other treatments, based on protein therapy, have a tendency to destroy the Neisserian Bacilli, but have no power to biochemically split and eliminate their dead bodies. Furthermore, they have no stimulating influence upon the system, with the consequence that the end products of the destroyed bacilli are not eliminated through the emunctories. The biochemical activity of Gonolin is of paramount importance as it eliminates all possibilities that the gonorrheal infection shall become chronic. This biochemical activity is insured exclusively through the use of Gonolin.

DIPHTHERIA ANTITOXIN, P. D. & CO.

CONCENTRATED AND REFINED (GLOBULIN) IN SYRINGE CONTAINERS OF RECENT DESIGN

NOTWITHSTANDING the fact that Diphtheria Antitoxin is specific, the mortality from diphtheria is still too high, and it rises with each day's delay in the administration of the antitoxin. If the dose is inadequate, cardiac failure may cause death, or paralysis may intervene, with its attendant incapacity.

For best results, the antitoxin must be highly concentrated, of low protein content, and of maximum potency.

Diphtheria Antitoxin, P. D. & Co., meets these requirements.

Its superior quality is the result of years of research endeavor and scrutinizing care in manufacture. The syringe container is especially designed for convenience and ease of manipulation under the most trying conditions, such as those attending the injection of antitoxin in children.

Diphtheria Antitoxin, P. D. & Co., is supplied in syringe containers of 1000 antitoxic units for prophylaxis, and 3000, 5000, 10,000 and 20,000 units for curative effect.

Our 22-page booklet, "Diphtheria—Prophylaxis and Treatment," is available to physicians upon request.

The definite place of fresh yeast in therapeutics

again established by exhaustive tests

A RECENT study at a Middle Western University has corroborated anew the findings of previous research as to the value of Fleischmann's Yeast for certain common ailments.

A large number of cases were studied. The investigators conclude, in part:

"From the results obtained we believe that yeast is of definite value in the treatment of furunculosis and chronic constipation.

" . . . In indigestion it seems to be of value in some cases. In some of the undernourished cases, yeast stimulated the appetite and seemed to facilitate absorption. From these results it appears that there is a definite place for yeast in Therapeutics."

Yeast showed very rapid results in quite a few of the series of cases studied by these scientists. The investigators say:

"Outside of the definite effects on the pathological conditions noted in the tables, yeast seems to produce some systemic effect. Many of the patients reported either a marked improvement in appetite or an increased sense of well-being."

Fleischmann's Yeast acts as a corrective for the too highly concentrated foods of today. In cases of constipation it increases the bulk and moisture of the faecal masses, tending to soften them, and diminishes the tendency toward absorption of putrefactive products. This last factor undoubtedly plays a role in the benefits noted from eating Fleischmann's Yeast for digestive disturbances.

As medical men have known for many years, yeast is remarkably effective for boils and skin disorders. And the combination of its qualities makes it highly beneficial as a general tonic, for so-called "run down condition."

* * *

YEAST may be eaten in a number of ways. The usual dosage is 2 or 3 cakes, one before each meal: in fruit juices, water or milk—spread on crackers—or just plain, nibbled from the cake. Naturally for constipation it is more effective in a glass of hot water (not scalding)—a cake night and morning.

A copy of our latest booklet on Yeast, for physicians, will be sent to you on your request. It contains authoritative scientific matter on the subject.

The Fleischmann Company, Dept. 259, 701 Washington Street, New York, N. Y.

*Note—A complete report of this investigation will be found in the May, 1926, issue of Archives of Therapeutics

INFANT DIET MEAD'S MATERIALS

Cow's Milk, Water and MEAD'S DEXTRI-MALTOSE

has been successfully used for years in the feeding of infants deprived of their natural food.

It is the carbohydrate of choice because it can be assimilated by the infant in greater amounts than other sugars.

It requires the least amount of energy on the part of the infant to assimilate it.

It is less likely to cause diarrhea than other forms of carbohydrate.

It produces a quicker gain in weight than any other form of carbohydrate.

Where certified milk or milk of equal quality cannot be obtained, MEAD'S POWDERED WHOLE MILK reliquefied by the addition of 4 level tablespoonfuls or one ounce of the dry powder to 7 ounces of sterile water may be substituted for the liquid milk called for in the formula.

The Mead Johnson Policy

MEAD'S Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant. Literature furnished only to physicians.

MEAD JOHNSON & COMPANY

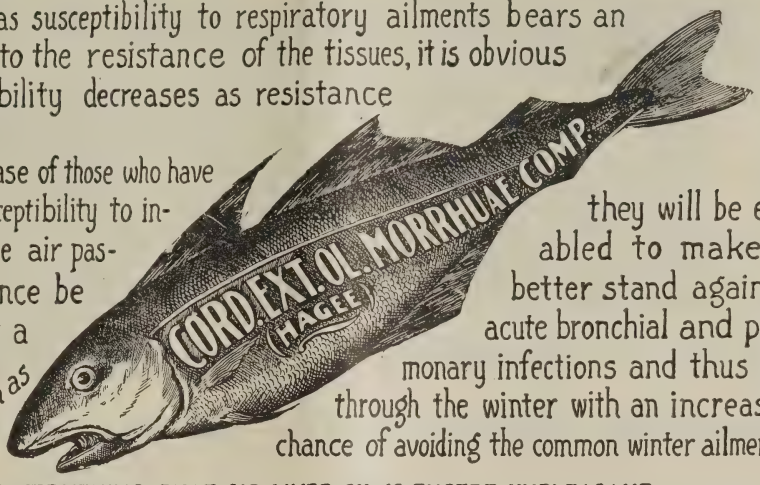
EVANSVILLE, INDIANA, U.S.A.

Manufacturers of Infant Diet Materials Exclusively

A BETTER STAND AGAINST RESPIRATORY DISEASES

Inasmuch as susceptibility to respiratory ailments bears an inverse ratio to the resistance of the tissues, it is obvious that susceptibility decreases as resistance increases.

If in the case of those who have an unusual susceptibility to infections of the air passages, resistance be augmented by a cod liver oil preparation such as



they will be enabled to make a better stand against acute bronchial and pulmonary infections and thus go through the winter with an increased chance of avoiding the common winter ailments.

EVERYTHING THAT COD LIVER OIL IS EXCEPT UNPLEASANT.

Easily Assimilated

EACH FLUID OUNCE OF HAGEE'S CORDIAL OF THE EXTRACT OF COD LIVER OIL COMPOUND CONTAINS THE EXTRACT OBTAINABLE FROM ONE-THIRD FLUID OUNCE OF COD LIVER OIL, (THE FATTY PORTION BEING ELIMINATED), FOUR GRAINS CALCIUM GLYCEROPHOSPHATE, FOUR GRAINS SODIUM GLYCEROPHOSPHATE, ONE-HALF GRAIN SALICYLIC ACID, (MADE FROM OIL WINTERGREEN), WITH GLYCERIN AND AROMATICS.

FREE FROM GREASE AND THE TASTE OF FISH

Supplied in sixteen ounce bottles only. Dispensed by all druggists.

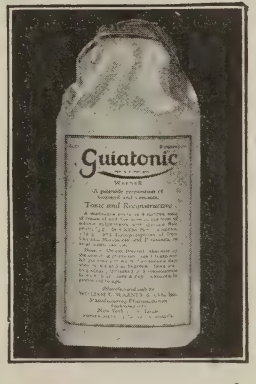
Katharmon Chemical Co., St. Louis, Mo.

The Menace of the Common Cold

is found mainly in its complications or consequences. "It is easy to tell when a cold starts, but no physician, however skilled, can tell when—or how—it will end!"

But under the prompt use of Guiatonic, the dangers of acute nose and throat infections can be largely removed. This is due chiefly to the aid and support it gives to the natural defensive and recuperative forces of the body.

Guiatonic is a splendid ally in fighting colds.



A palatable preparation of special salts of guaiacol and creosote which may be freely given to the weakest patient, without fear of gastric disturbance. *It contains no narcotics.*

Indicated in all depressed or debilitated conditions, or whenever a tonic is required.

Guiatonic

A liberal sample for testing free to physicians. William R. Warner & Company, Inc. Manufacturing Pharmaceutists since 1856. 113-123 West 18th Street, New York City.

Atophan

TRADE MARK
Reg. U. S. Pat. Off.

Influenza (Grippe) Is Again With Us for Several Months' Intermittent Stay—

Have you ever given ATOPHAN a chance to display its superior and safe anti-inflammatory, decongestive and pain-relieving action in the management of this hardy perennial?

For Influenza (Grippe) and the "colds" which so often lead to it, ATOPHAN is best prescribed in form of

ATOPHAN-ACETYLSALICYLIC ACID COMPOUND TABLETS S. & G.

in which the conjoint and correctly dosaged use of a universally approved, active anti-pyretic rounds out the good work of ATOPHAN.

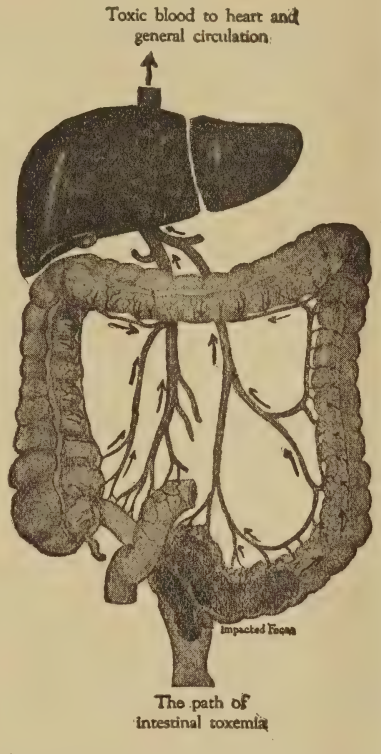
INTESTINAL STASIS

INTESTINAL STASIS exists if the food residue does not reach the cecum within 12 hours and is not evacuated in 24 hours.



The path of intestinal toxemia

CAUSES

Bio-Physical. (1) Intestinal toxemia, (2) chronic appendical disease, (3) coloptosis, (4) insufficient exercise, (5) senile muscle changes, (6) improper diet.

Mechanical. (a) Congenital muscular atrophy, (b) constricting Jackson's membranes, (c) membranous veils about the hepatic flexure, (e) torsions and twistings of the transverse colon, (f) multiple diverticulae.

Though daily evacuations occur, the cecum may take from 50 to 100 hours to empty. In such cases intestinal invalidism comes on insidiously.

Only mild, depurative measures should be used to relieve intestinal stasis. Drastic therapy is dangerous. And as intestinal stasis implies mechanical friction, this calls for lubrication.

Viscosity specifications for Nujol, the ideal lubricant, were determined only after exhaustive clinical tests in which the consistencies tried ranged from a water-like fluid to a jelly. The name "Nujol" is a guarantee to the profession of absolute purity and insures that the viscosity of the liquid petrolatum so labeled is physiologically correct at body temperature and in accord with the opinion of leading medical authorities. Nujol is the highest quality liquid petrolatum made by the Standard Oil Co. (New Jersey).

Nujol

***Friedenthal, H.—Ueber die Eigenschaften künstlicher Milchersera und ueber die Herstellung eines künstlichen Menschenmilchersatzes. Zentralb. f. Physiol., Vol. 24—1910—page 687.

PHYSICIANS agree that breast milk is the ideal food for the human infant. When breast milk is not available, or as a supplement to breast milk, S. M. A. may be prescribed as an able substitute for feeding normal, full-term infants, or in the milder cases of malnutrition.

S. M. A. is not simply dried cow's milk, but is an adaptation to breast milk, both physically and chemically. It not only has the correct percentage of fat, protein and carbohydrate, but also the physical characteristics of breast milk as well. S. M. A. has the same hydrogen ion concentration, a depression of freezing point and a reaction point within the limits of those found in breast milk.

It is only natural then that the nutritional results with S. M. A. should approach those of breast milk, that the buffer curve should be practically identical to that of breast milk and that the intestinal flora should be like that of breast milk. In addition, S. M. A. prevents rickets and spasmophilia.

We invite you to try S. M. A. in your own practice. Literature and liberal trial package sent upon request.
